

Lecture 6: Document Similarity & Clustering

Pilsung Kang

School of Industrial Management Engineering
Korea University

AGENDA

01 Document Similarity

02 Clustering Overview

03 Partition-based Clustering

04 Hierarchical Clustering

05 Density-based Clustering

06 Spectral Clustering

07 Self-Organizing Map

Document Similarity: Backgrounds

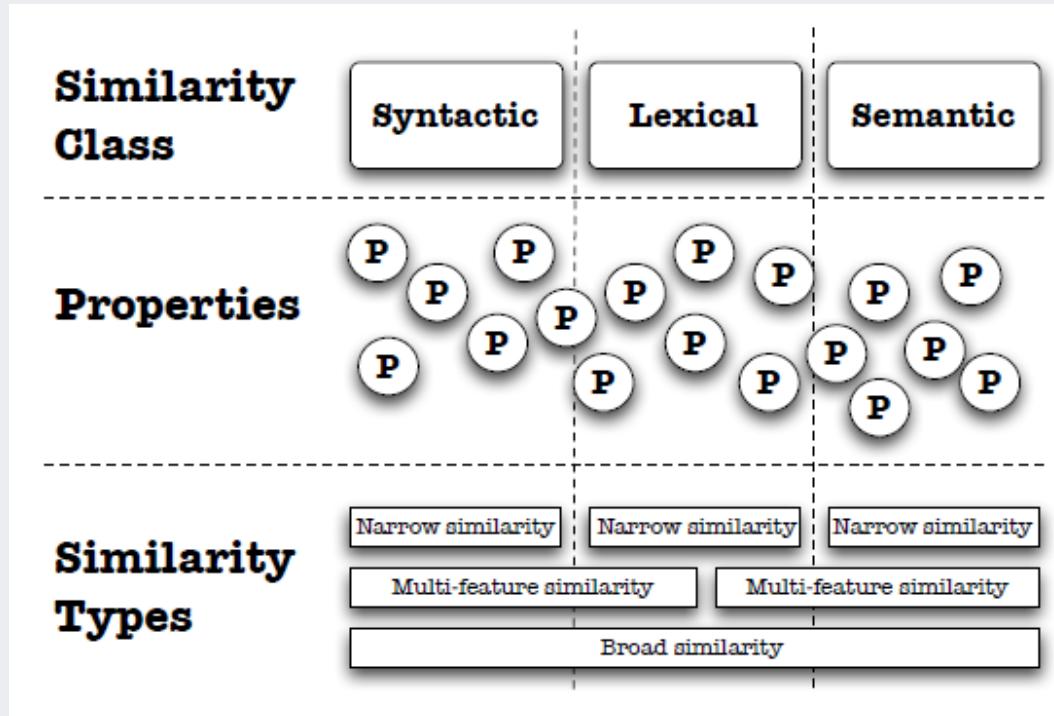

- Similarity in the Cognitive Sciences
 - ✓ Two objects falling under different concepts are similar because they have many **properties** in common
 - Similarity between two objects increases as a function of the number of properties they share
 - Properties can be treated as independent and additive
 - **The properties determining similarity are all roughly the same level of abstractness**
 - Similarities should be sufficient to describe conceptual structure

Document Similarity

- Problem
 - ✓ Given two text documents, how similar are they?
 - ✓ Example
 - d1: ant, ant, bee
 - d2: dog, bee, dog, hog, dog, ant, dog
 - d3: cat, gnu, dog, eel, fox
- Similarity between text documents
 - ✓ Used for search engines, text corpus visualizations, filtering, sorting, and retrieving rely fundamentally on similarity measures
 - ✓ A number of candidate models exist, not been assessed in terms of their ability to emulate human judgments of similarity

Document Similarity

- Similarity Measure
 - ✓ A function which computes the **degree of similarity** between a pair of vectors (documents)
 - ✓ There are a large number of similarity measures proposed in the literature, because the **best** similarity measure **does not exist** (yet!)

Document Similarity

- Term similarity
 - ✓ Two documents are similar if they contain some of the same terms
 - ✓ Possible measures of similarity might take into consideration
 - The length of the document
 - The number of terms in common
 - Whether the terms are common or unusual
 - How many times each term appears
- Vector space model
 - ✓ A document is represented in n-dimensional space, where n is the number of different terms/features used to index a set of documents

Document Similarity I: Binary Similarity Models

- Notation

- ✓ x_{ik} : the frequency of the term k in the document i
- ✓ t_{ik} : 1 if $x_{ik} > 0$, 0 otherwise
- ✓ $a_{ij} : \sum_k t_{ik} t_{jk}$, the number of words/N-grams in the corpus that are common to both documents
- ✓ $b_{ij} : \sum_k t_{ik} (1 - t_{jk})$, the number of words/N-grams that are presented in the document i but not in the document j
- ✓ $c_{ij} : \sum_k (1 - t_{ik}) t_{jk}$, the number of words/N-grams that are presented in the document j but not in the document i
- ✓ $d_{ij} : \sum_k (1 - t_{ik})(1 - t_{jk})$, the number of words/N-grams that are presented in neither documents

Document Similarity I: Binary Similarity Models

- Example

Freq.	D ₁	D ₂	D ₃
T ₁	3	0	2
T ₂	0	0	1
T ₃	5	3	0
T ₄	0	2	1
T ₅	0	1	2

Binary	D ₁	D ₂	D ₃
T ₁	1	0	1
T ₂	0	0	1
T ₃	1	1	0
T ₄	0	1	1
T ₅	0	1	1

✓ Between D₁ and D₂

- $a_{12} = 1, b_{12} = 1, c_{12} = 2, d_{12} = 1$

Document Similarity I: Binary Similarity Models

- Common Features Model

- ✓ Similarity is measured by the proportion of common features

$$s_{ij}^{common} = \frac{a_{ij}}{a_{ij} + b_{ij} + c_{ij} + d_{ij}}$$

- Ratio Model (Jaccard coefficient in binary format)

- ✓ The ratio of common to common and distinctive features

$$s_{ij}^{ratio} = \frac{a_{ij}}{a_{ij} + b_{ij} + c_{ij}}$$

Common	D ₁	D ₂	D ₃
D ₁	-	1/5	1/5
D ₂		-	2/5
D ₃			-

Ratio	D ₁	D ₂	D ₃
D ₁	-	1/4	1/5
D ₂		-	2/5
D ₃			-

Document Similarity I: Binary Similarity Models

- Simple Matching Coefficient

- ✓ Two documents become more dissimilar to the extent that one document has a feature that the other does not

$$S_{ij}^{smc} = \frac{a_{ij} + d_{ij}}{a_{ij} + b_{ij} + c_{ij} + d_{ij}}$$

SMC	D ₁	D ₂	D ₃
D ₁	-	2/5	1/5
D ₂		-	2/5
D ₃			-

- For more binary similarity measures, see the Appendix A

Document Similarity 2: Count Similarity Models

- Jaccard similarity

- ✓ The ratio of common to common and distinctive features

$$s_{ij}^{Jaccard} = \frac{\sum_k \min(x_{ik}, x_{jk})}{\sum_k \max(x_{ik}, x_{jk})}$$

- Overlap similarity

- ✓ Measures the overlap between two document defined as the size of the intersection divided by the smaller of the size of the two documents

$$s_{ij}^{overlap} = \frac{\sum_k \min(x_{ik}, x_{jk})}{\min(\sum_k x_{ik}, \sum_k x_{jk})}$$

Jaccard	D1	D2	D3
D1	-	3/11	2/12
D2		-	2/9
D3			-

Overlap	D1	D2	D3
D1	-	3/6	2/6
D2		-	2/6
D3			-

Document Similarity 2: Count Similarity Models

- Cosine similarity

- ✓ The similarity between two document is a function of the angle between their vectors in the vector space

$$S_{ij}^{cosine} = \frac{\sum_k (x_{ik} \times x_{jk})}{\sqrt{(\sum_k x_{ik}^2)(\sum_k x_{jk}^2)}}$$

Cosine	D ₁	D ₂	D ₃
D ₁	-	0.6875	0.3254
D ₂		-	0.3380
D ₃			-

AGENDA

01 Document Similarity

02 Clustering Overview

03 Partition-based Clustering

04 Hierarchical Clustering

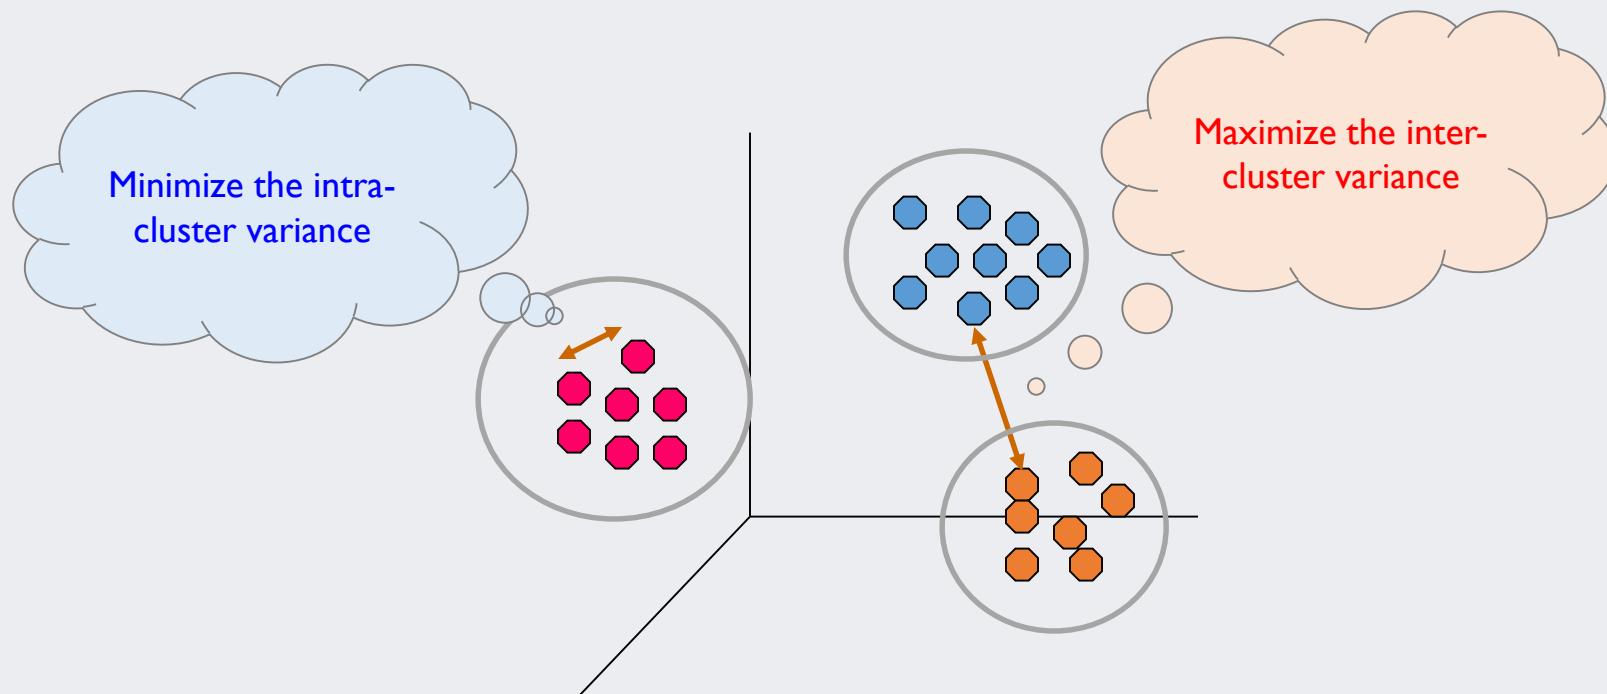

05 Density-based Clustering

06 Spectral Clustering

07 Self-Organizing Map

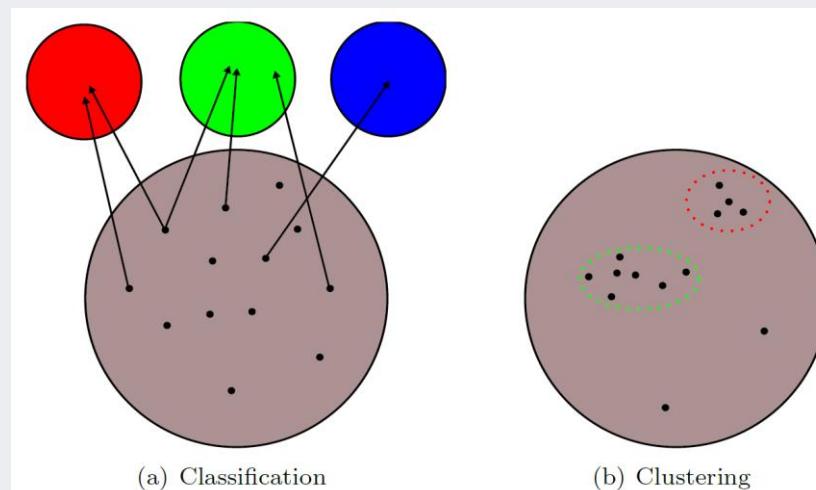

Type of Clustering

- What is clustering?
 - ✓ Find groups of objects such that the objects in a group will be similar (or related) to one another and different from (or unrelated to) the objects in other groups

Document Clustering

- Document clustering
 - ✓ Aims to discover natural grouping, presenting an overview of the classes (topics) in a collection of documents
- Classification (Categorization) vs. Clustering
 - ✓ Classification: The number of classes (and their properties) is known a priori, and documents are assigned to one of them (supervised learning)
 - ✓ Clustering: neither the number, properties, or membership of classes known in advance (unsupervised learning)

Clustering Overview

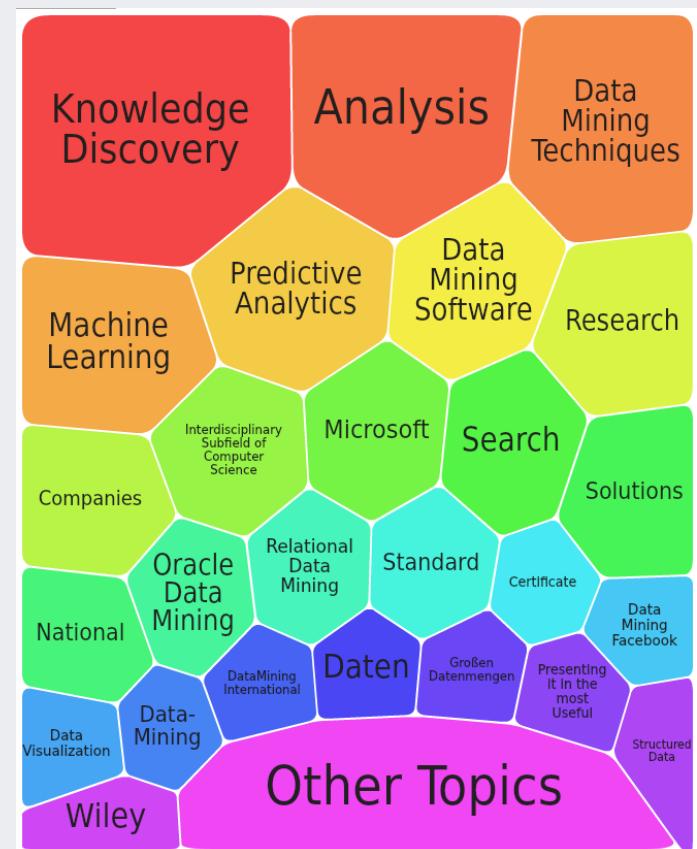

- Where are clustering used?

✓ “Understanding”

- Related documents for browsing
- Genes and proteins for similar functionalities
- Stocks with similar price fluctuation

Query: israel
Documents: 272, Clusters: 15, Average Cluster Size: 15.1 documents

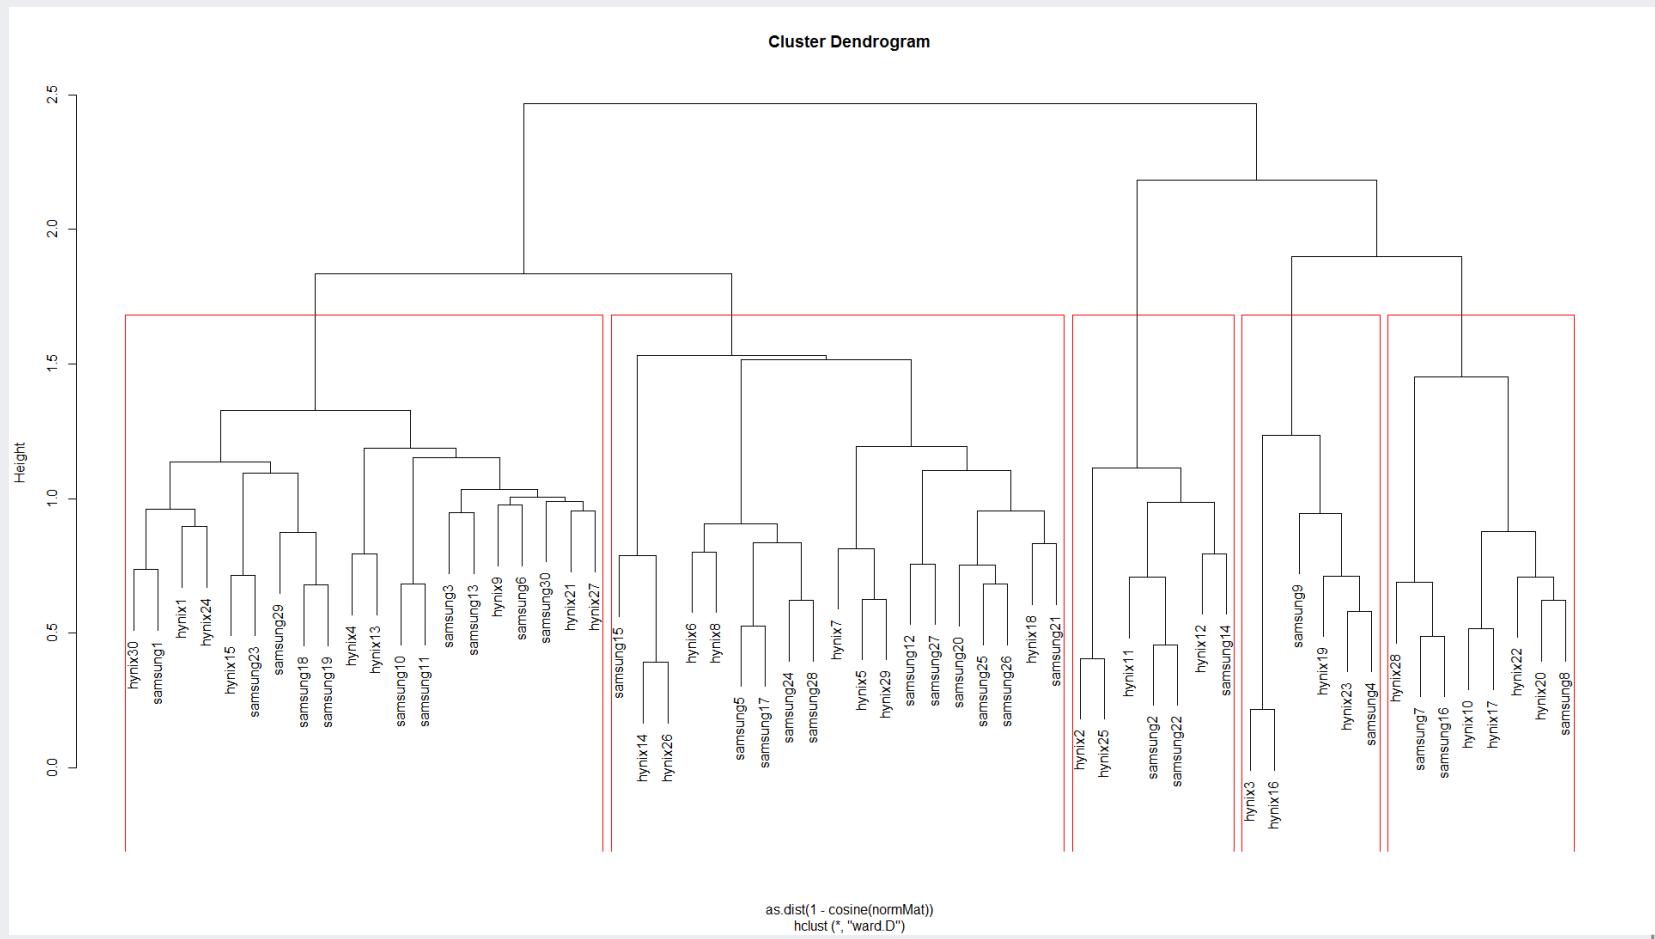

Cluster	Size	Shared Phrases and Sample Document Titles
1 View Results Refine Query Based On This Cluster	16	Society and Culture (56%), Faiths and Practices (56%), Judaism (69%), Spirituality (56%); Religion (56%), organizations (43%) <ul style="list-style-type: none"> ● Ahavat Israel - The Amazing Jewish Website! ● Israel and Judaism ● Judaica Collection
2 View Results Refine Query Based On This Cluster	15	Ministry of Foreign Affairs (33%), Ministry (87%) <ul style="list-style-type: none"> ● Publications and Data of the BANK OF ISRAEL ● Consulate General of Israel to the Mid-Atlantic Region ● The Friends of Israel Gospel Ministry

Clustering Overview

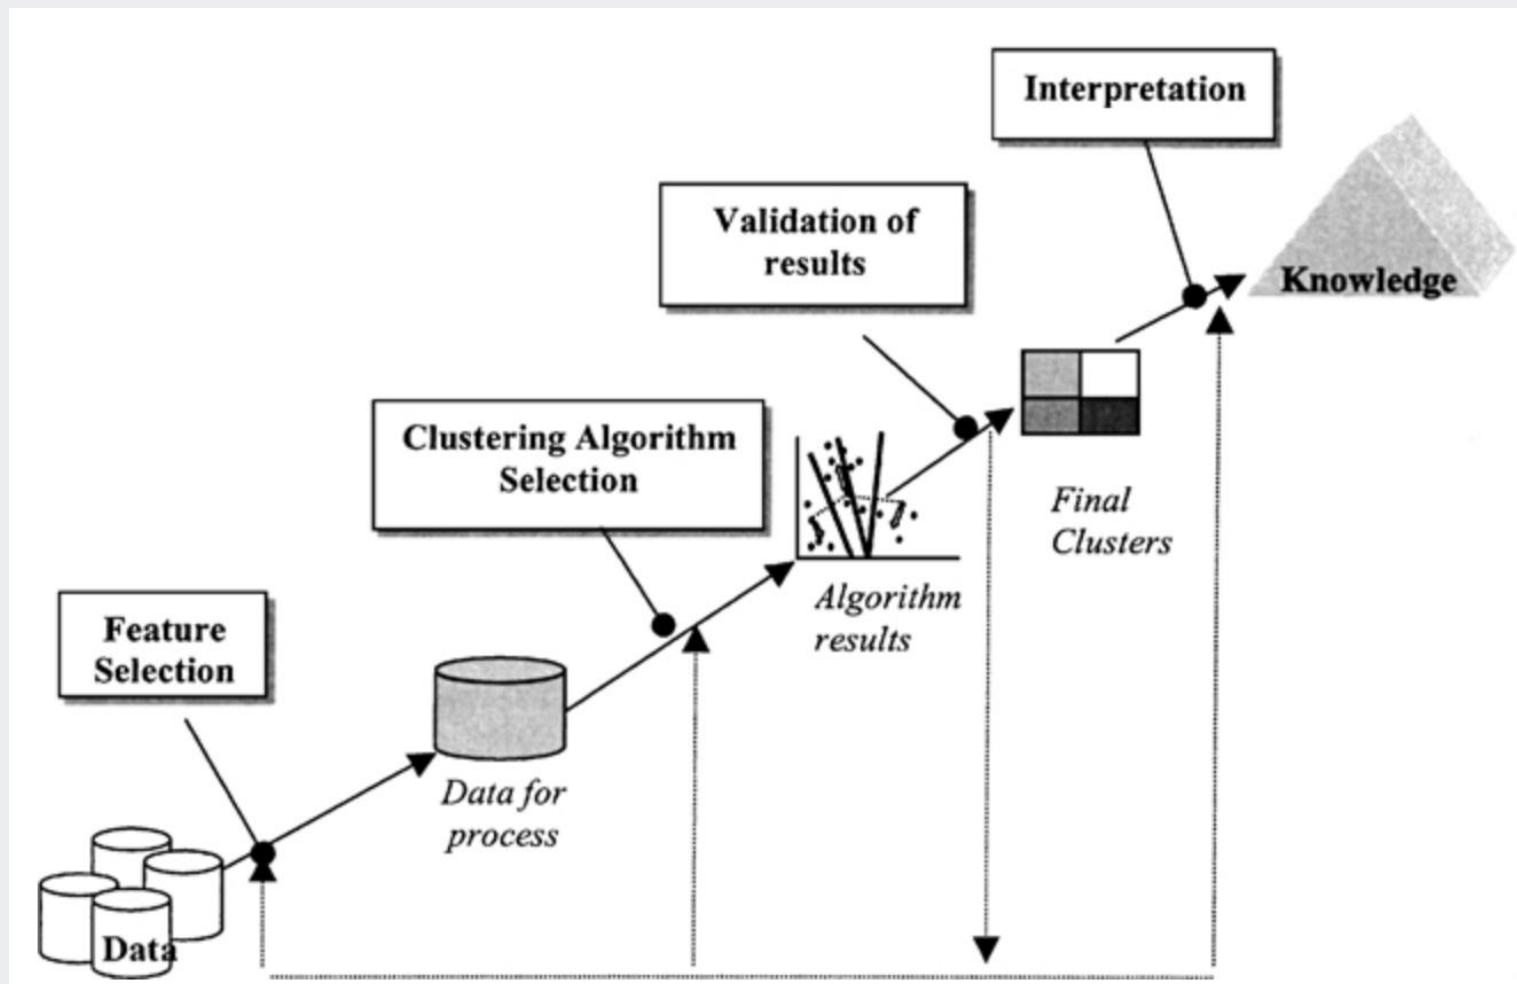

- Where are clustering used?

✓ Strategic planning: Patent Analysis

Clustering Overview

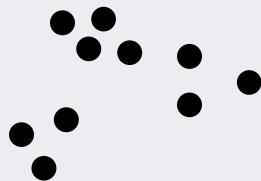

- Clustering procedure

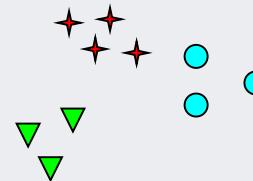

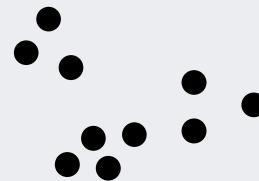

Clustering Overview

- Issues on clustering

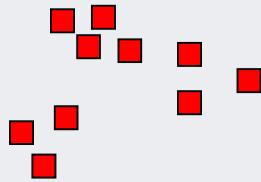

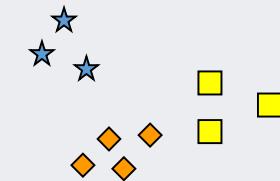

✓ How many clusters are optimal?

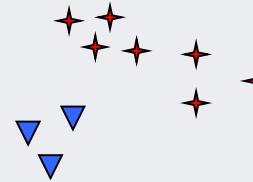

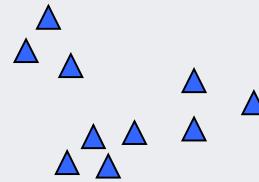

How many clusters?

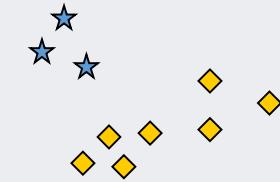

Six Clusters

Two Clusters

Four Clusters

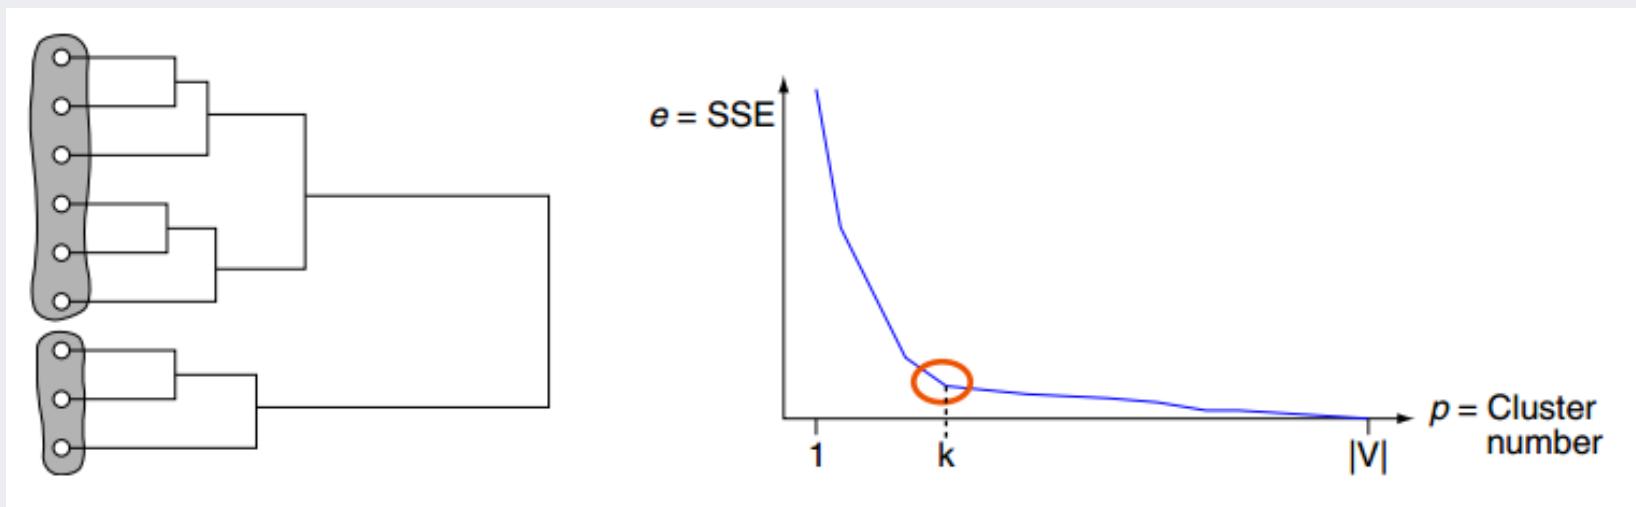

Clustering Overview

- Issues on clustering

- ✓ How many clusters are optimal?

- Use the validity plot for various number of clusters
 - In general, set the elbow point as the optimal number of clusters

Clustering: Issues

- How to evaluate the clustering result?
 - ✓ There is no globally accepted validity measure
 - ✓ Because clustering is an unsupervised learning task, we do not know the exact answer
- Three categories for clustering validity measures
 - ✓ External: Compare the clustering structure with the known answer (**unrealistic**)
 - ✓ Internal: Focusing on the **compactness** of clusters
 - ✓ Relative: Focusing on both the **compactness** of clusters and **separation** between clusters

Clustering Overview

- Issues on clustering

- ✓ How to evaluate the clustering results?

- External: Analyze how close is a clustering to a reference
 - Internal: Analyze intrinsic characteristic of a clustering
 - Analyze the sensitivity (of internal measures) during clustering generation

External	Internal	Relative
<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
<input type="checkbox"/> Rand Statistic	<input type="checkbox"/> Cophenetic Correlation Coefficient	<input type="checkbox"/> Dunn family of indices
<input type="checkbox"/> Jaccard Coefficient	<input type="checkbox"/> Sum of Squared error (SSE)	<input type="checkbox"/> Davies-Bouldin (DB) index
<input type="checkbox"/> Folks and Mallows index	<input type="checkbox"/> Cohesion and separation	<input type="checkbox"/> Semi-partial R-squared
<input type="checkbox"/> (Normalized) Hurbert Γ statistic		<input type="checkbox"/> SD validity index
		<input type="checkbox"/> Silhouette

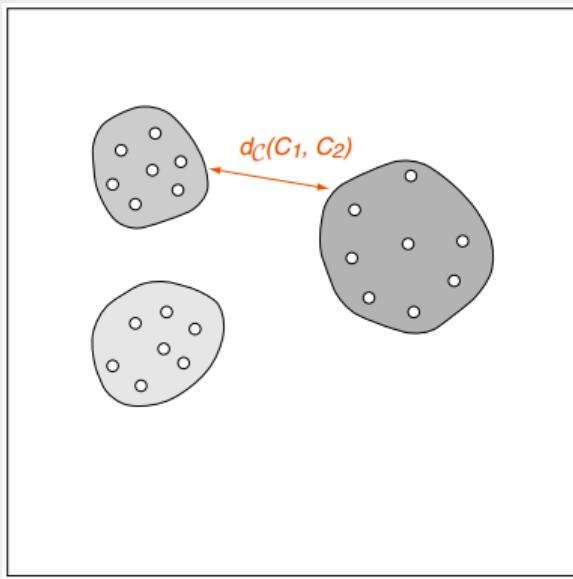

- ✓ There is no single best metric for all clustering tasks

- For more definitions of the clustering validity measures, see the Appendix B.

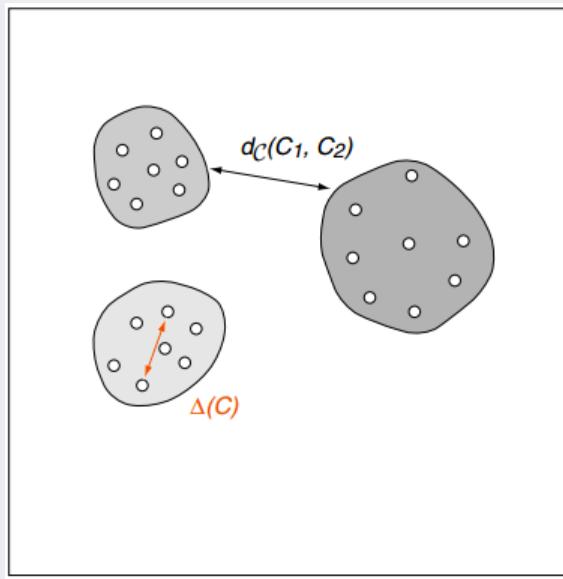

Clustering Validity Index

- Measurements

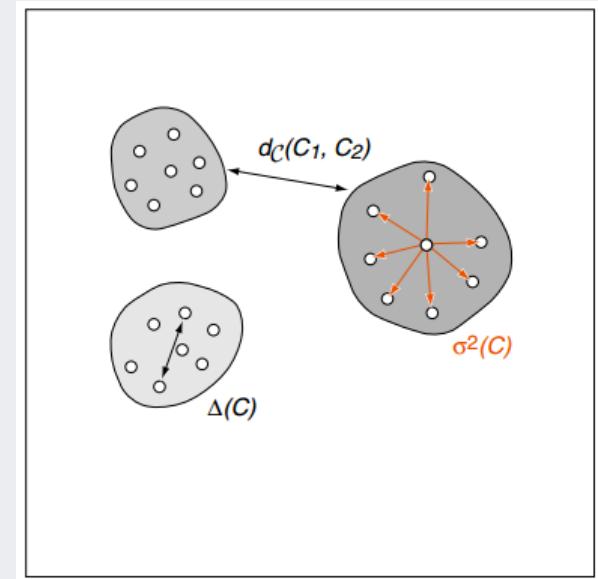

Distance between two clusters

Diameter of a cluster

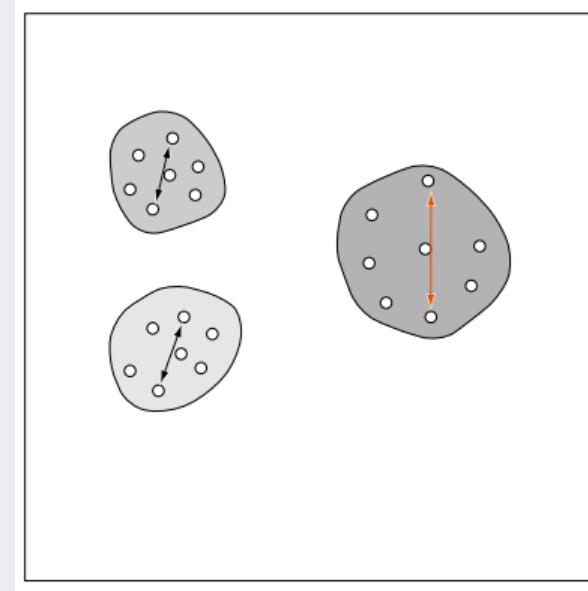

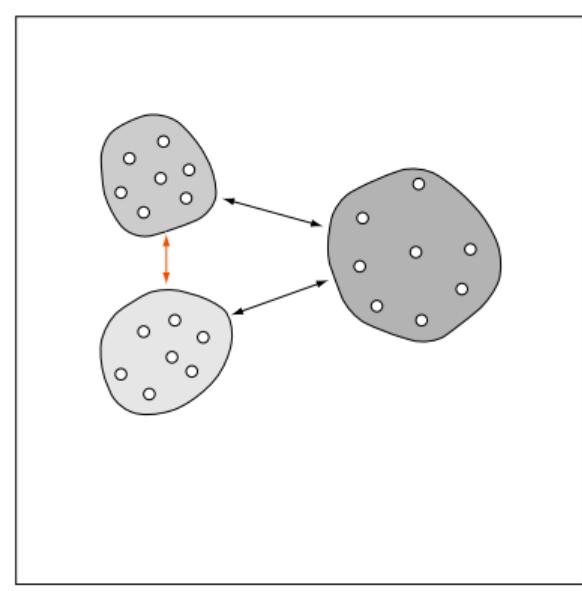

Scatter within a cluster (SSE)

Clustering Validity Index

- Dunn Index

$$I(\mathcal{C}) = \frac{\min_{i \neq j} \{d_{\mathcal{C}}(C_i, C_j)\}}{\max_{1 \leq l \leq k} \{\Delta(C_l)\}},$$

$I(\mathcal{C}) \rightarrow \max$

$$I(\mathcal{C}) = \frac{\min_{i \neq j} \{d_{\mathcal{C}}(C_i, C_j)\}}{\max_{1 \leq l \leq k} \{\Delta(C_l)\}},$$

$I(\mathcal{C}) \rightarrow \max$

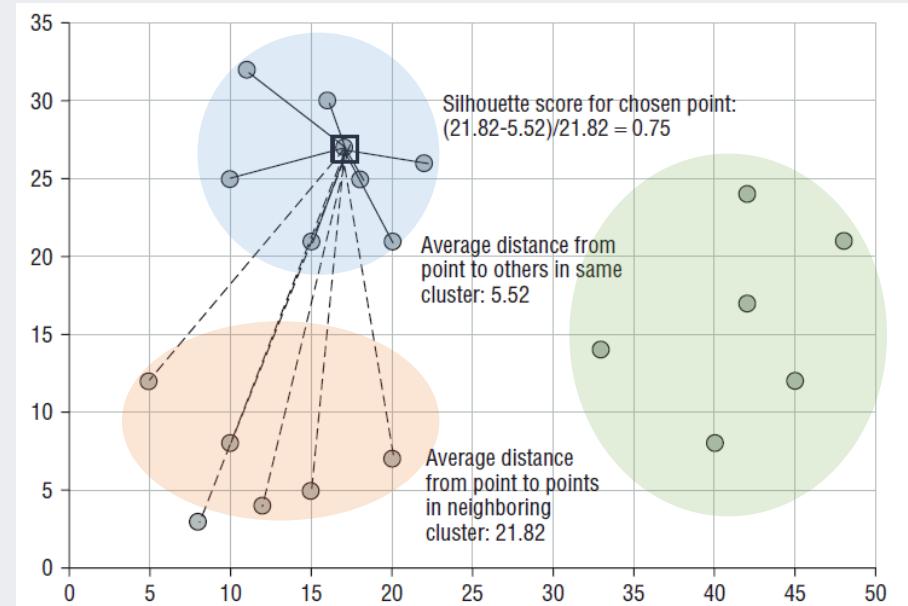

Clustering: Issues

- Clustering Validity Measure Example: Silhouette

- ✓ $a(i)$: the average distance between an instance i and the other instances in the same cluster
- ✓ $b(i)$ the minimum of the average distances between an instance i and the instances in a cluster to which the instance i does not belong

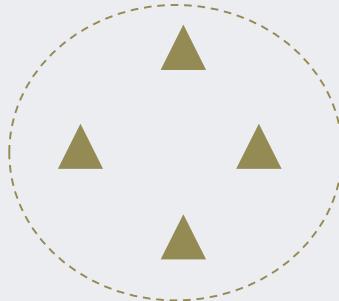

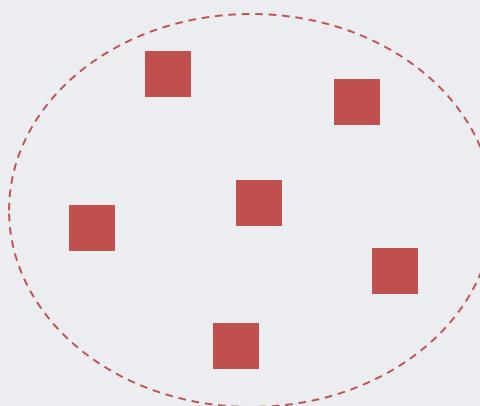

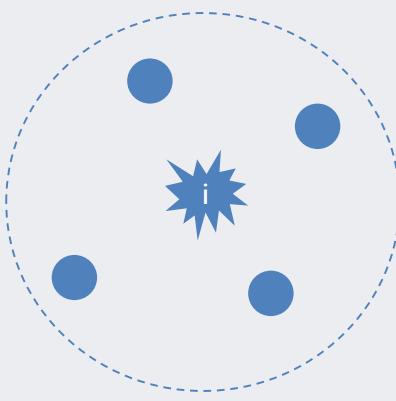

$$s(i) = \frac{b(i) - a(i)}{\max\{a(i), b(i)\}}$$

$$s(i) = \begin{cases} 1 - a(i)/b(i), & \text{if } a(i) < b(i) \\ 0, & \text{if } a(i) = b(i) \\ b(i)/a(i) - 1, & \text{if } a(i) > b(i) \end{cases}$$

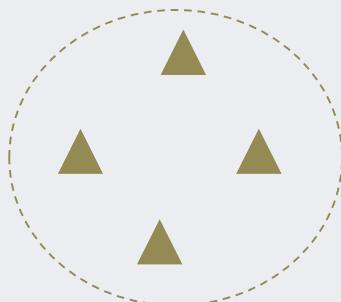

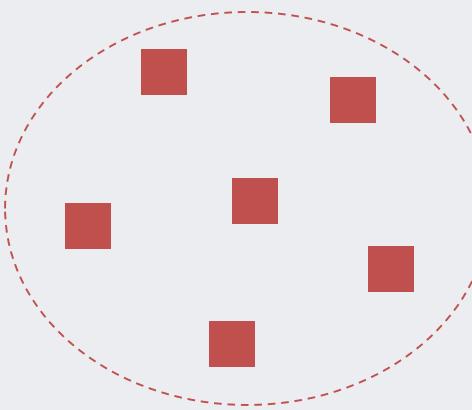

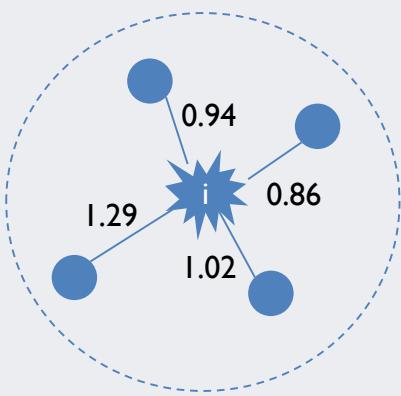

Clustering: Issues

- Clustering Validity Measure Example: Silhouette

Clustering: Issues

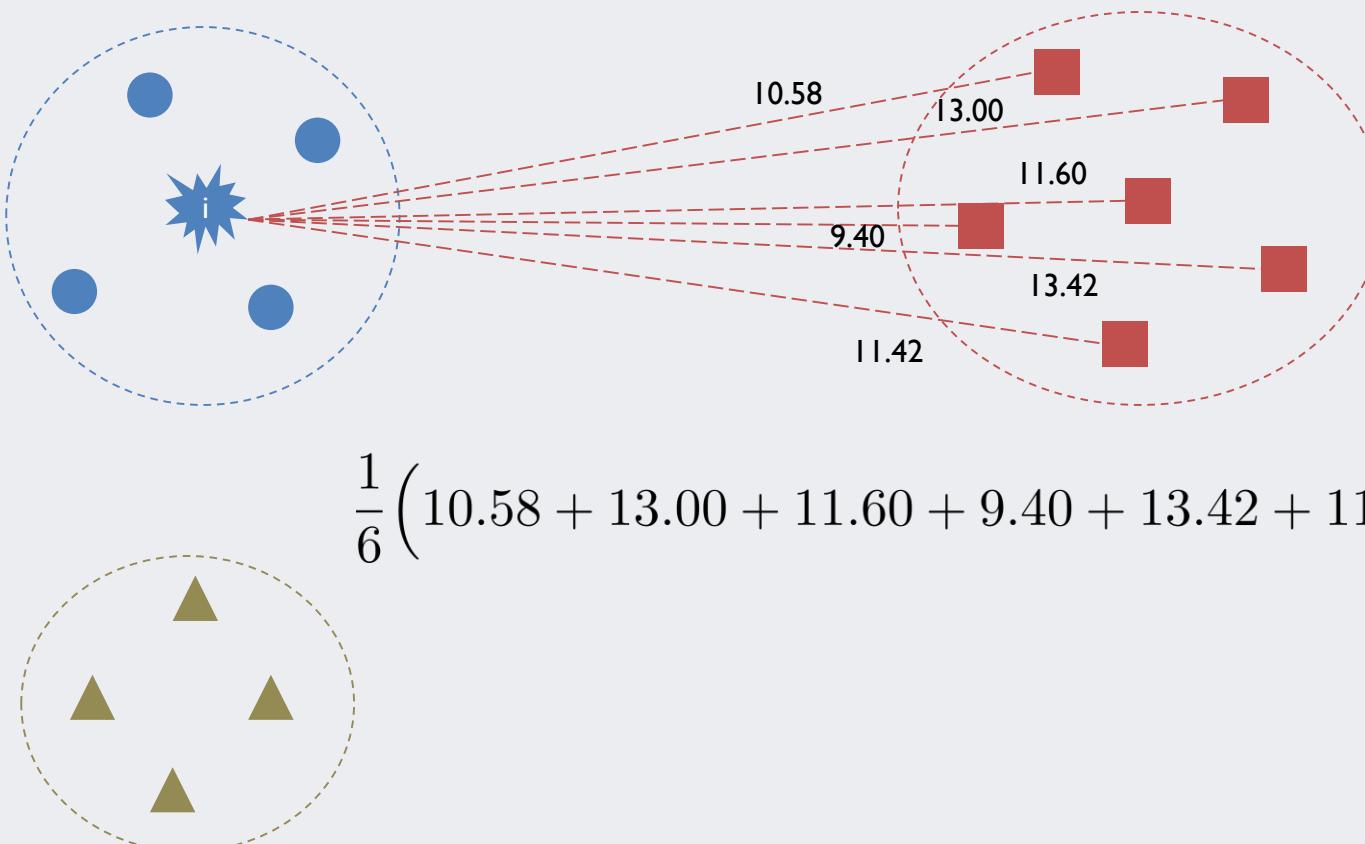

- Clustering Validity Measure Example: Silhouette

$$a(i) = \frac{1}{4} (0.94 + 0.86 + 1.02 + 1.29) = 1.03$$

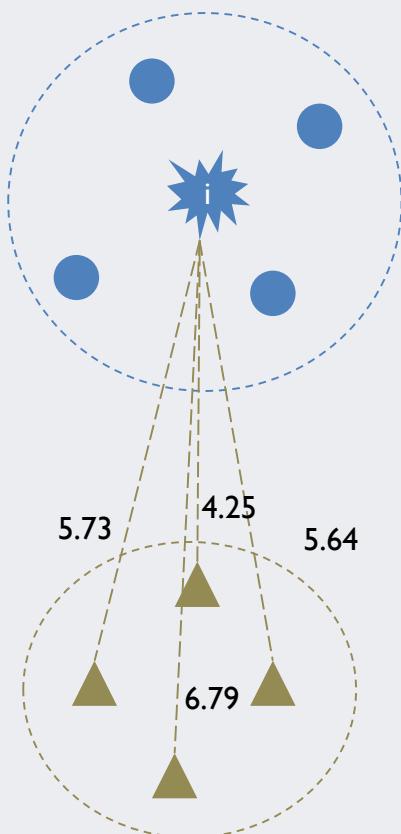

Clustering: Issues

- Clustering Validity Measure Example: Silhouette

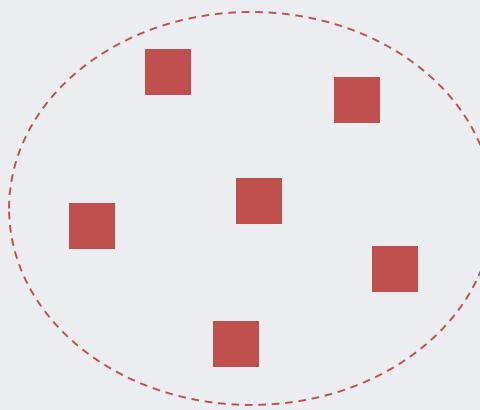

Clustering: Issues

- Clustering Validity Measure Example: Silhouette

$$\frac{1}{4} (5.73 + 6.79 + 4.25 + 5.64) = 5.60$$

$$b(i) = \min(11.57, 5.60) = 5.60$$

$$\begin{aligned}s(i) &= \frac{5.60 - 1.03}{\max(1.03, 5.60)} \\&= \frac{4.57}{5.60} = 0.82\end{aligned}$$

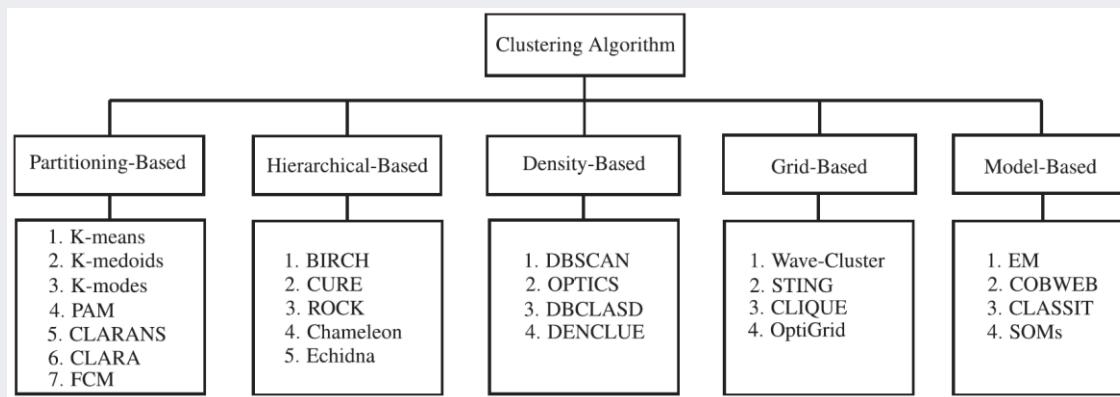

Type of Clustering

Fahad et al. (2014)

- Hard Clustering vs. Soft Clustering

- ✓ Hard Clustering (Crisp Clustering)

- Produces disjoint (non-overlapping) clusters
 - Each document belongs to only one cluster

- ✓ Soft Clustering (Fuzzy Clustering)

- Produces overlapping clusters
 - A document can have multiple cluster memberships
 - Techniques used in topic modeling (pLSI, LDA, etc.)

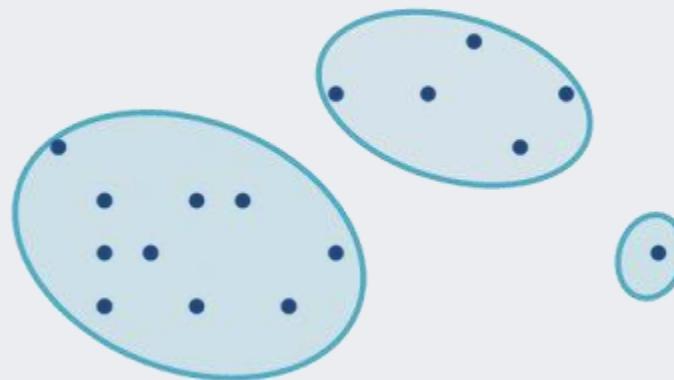

Type of Clustering

- Type of clustering techniques

- ✓ Partitional clustering

- Divide data into non-overlapping subsets such that each data object is in exactly one subset

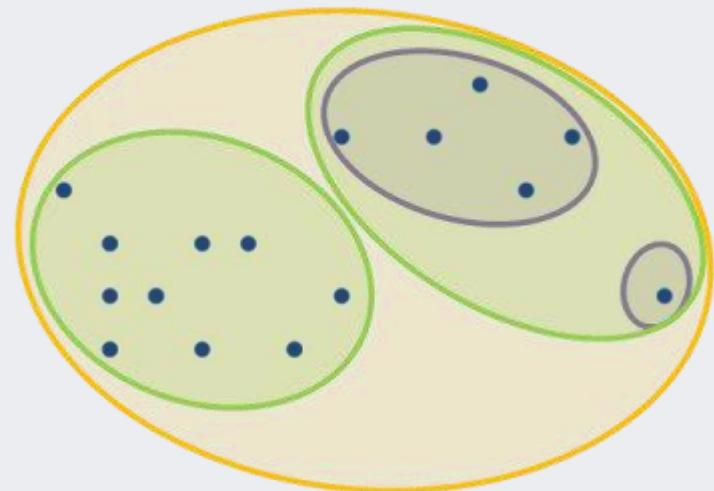

Partitional Clustering

- ✓ Hierarchical clustering

- A set of nested clusters organized as a hierarchical tree

Hierarchical Clustering

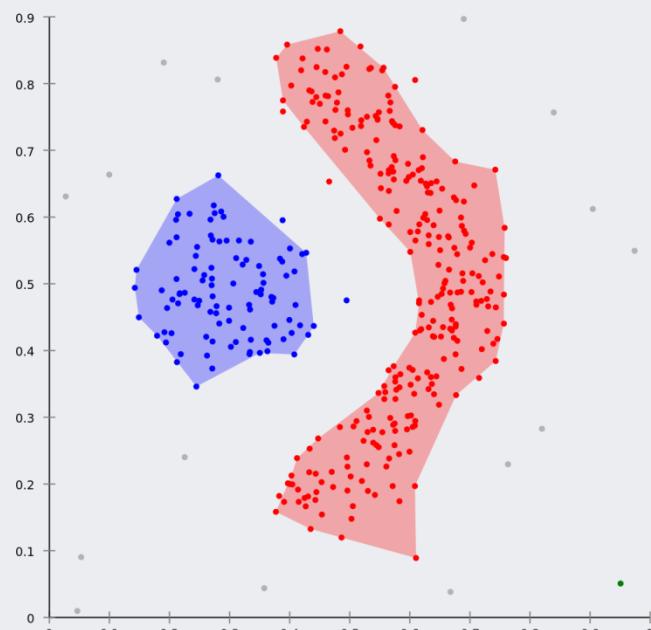

Type of Clustering

- Type of clustering techniques

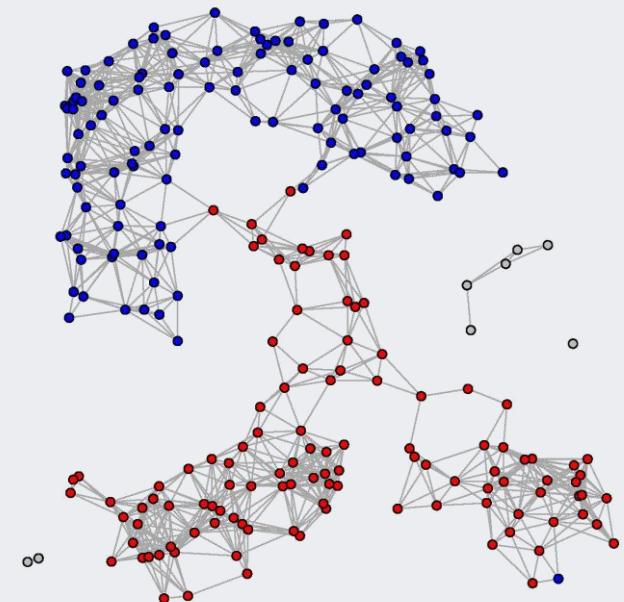

- ✓ Density-based Clustering

- Considers relative density of data space

- ✓ Graph-based Clustering

- Define a subset in a nodes in a graph such that nodes in the same cluster are densely connected whereas nodes in different clusters are sparsely connected

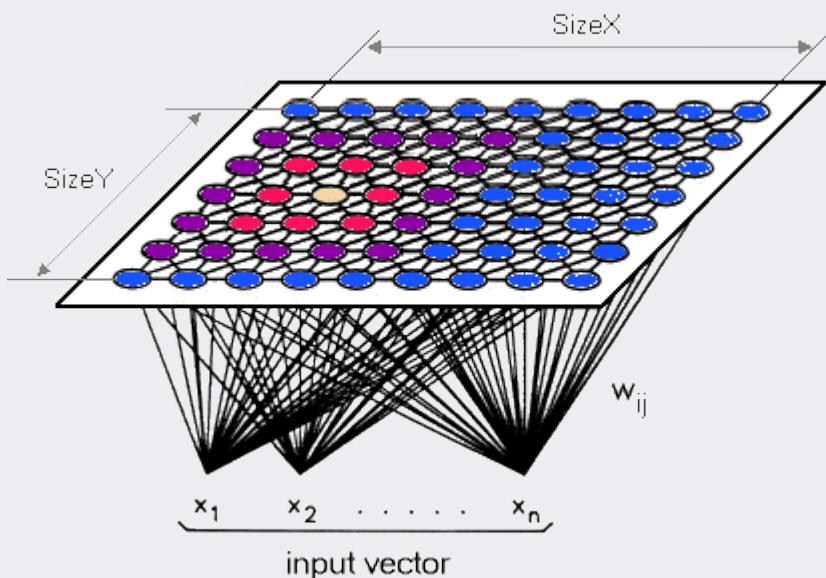

Type of Clustering

- Type of clustering techniques

- ✓ Self-Organizing Map (SOM)

- Clustering data and ordering of the cluster centers in a two dimensional grid through neural network-based learning methods

AGENDA

- 01 Document Similarity
- 02 Clustering Overview
- 03 Partition-based Clustering
- 04 Hierarchical Clustering
- 05 Density-based Clustering
- 06 Spectral Clustering
- 07 Self-Organizing Map

K-Means Clustering

- K-Means Clustering (KMC)

- ✓ Partitional clustering approach

- Each cluster is associated with a centroid
- Each point is assigned to the cluster with the closest centroid
- Number of cluster, K, must be specified

$$\mathbf{X} = C_1 \cup C_2 \dots \cup C_K, \quad C_i \cap C_j = \emptyset, \quad i \neq j$$

$$\arg \min_{\mathbf{C}} \sum_{i=1}^K \sum_{\mathbf{x}_j \in C_i} \|\mathbf{x}_j - \mathbf{c}_i\|^2$$

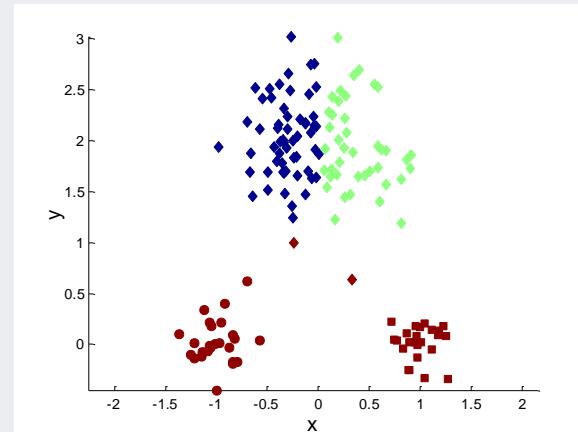

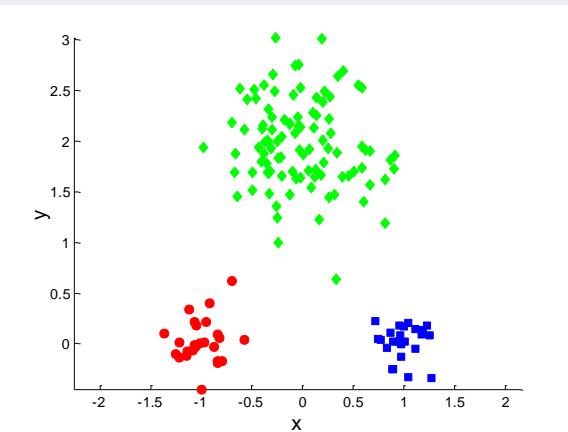

K-Means Clustering

- K-Means Clustering Procedure

- ✓ Algorithm

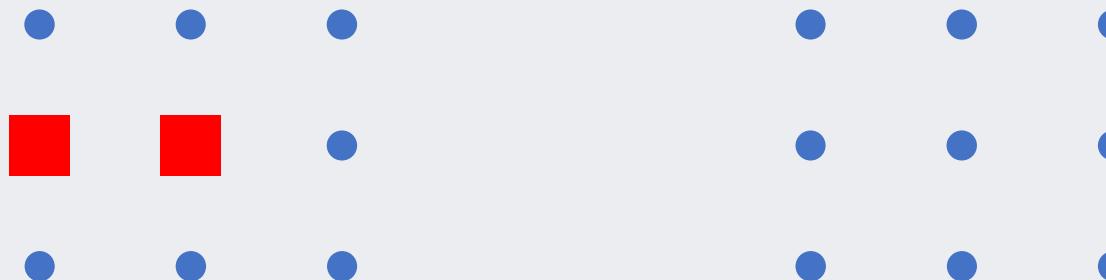

- ```
1: Select K points as the initial centroids.
2: repeat
3: Form K clusters by assigning all points to the closest centroid.
4: Recompute the centroid of each cluster.
5: until The centroids don't change
```

- Initial centroids are often **chosen randomly**: clustering results vary according to the initial centroid selection

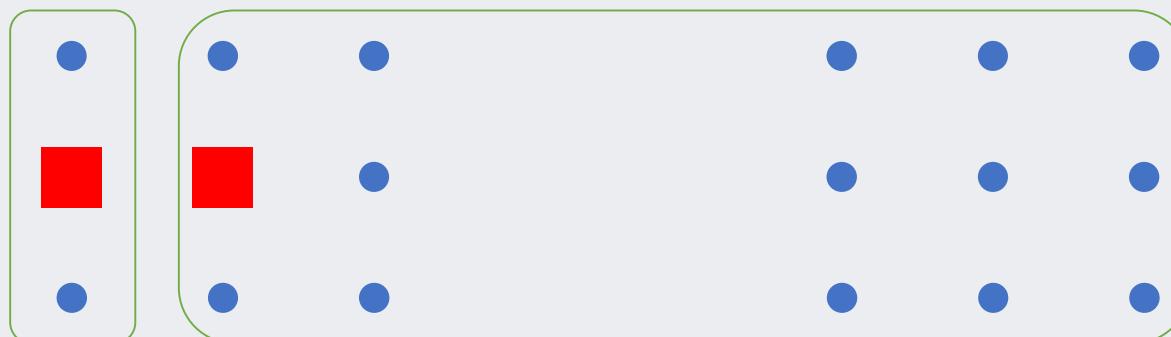

# K-Means Clustering

- KMC Example
  - ✓ Step 1: Initialize K centroids

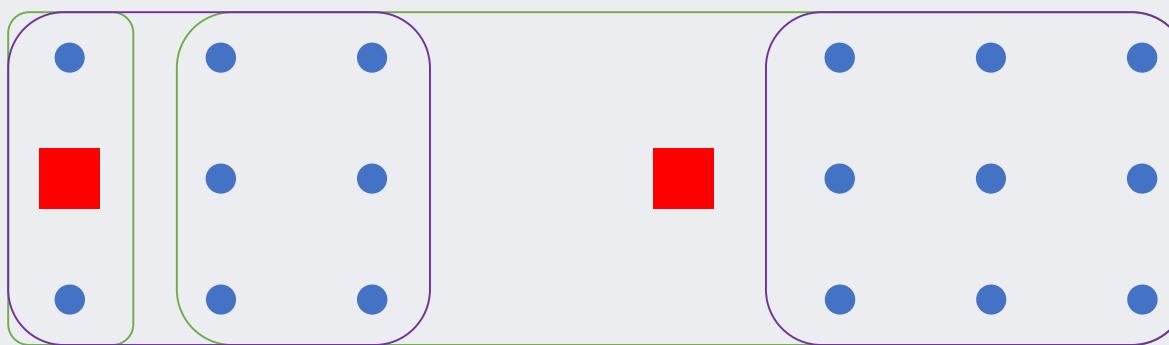

- ✓ Step 2-1 (1<sup>st</sup> round): Assign all instances to their closest centroid
- ✓ Step 2-2 (1<sup>st</sup> round): Re-compute the centroids with the assigned instances

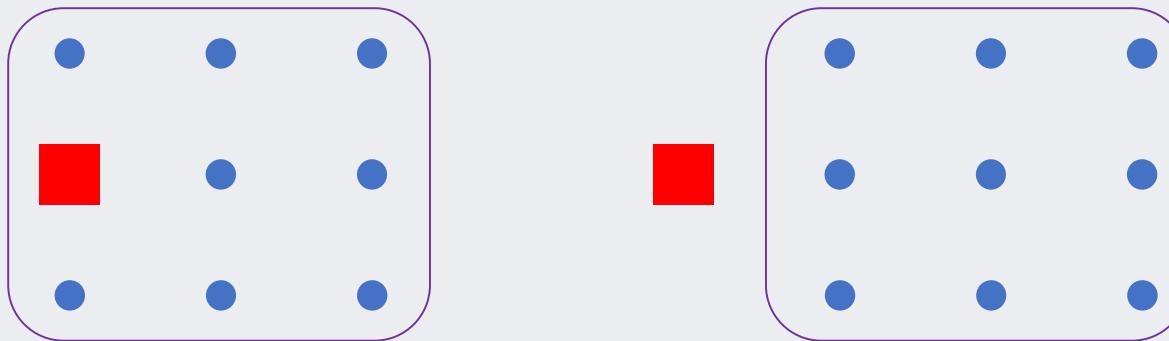

# K-Means Clustering

- KMC Example

- ✓ Step 2-1 (2<sup>nd</sup> round): Assign all instances to their closest centroid

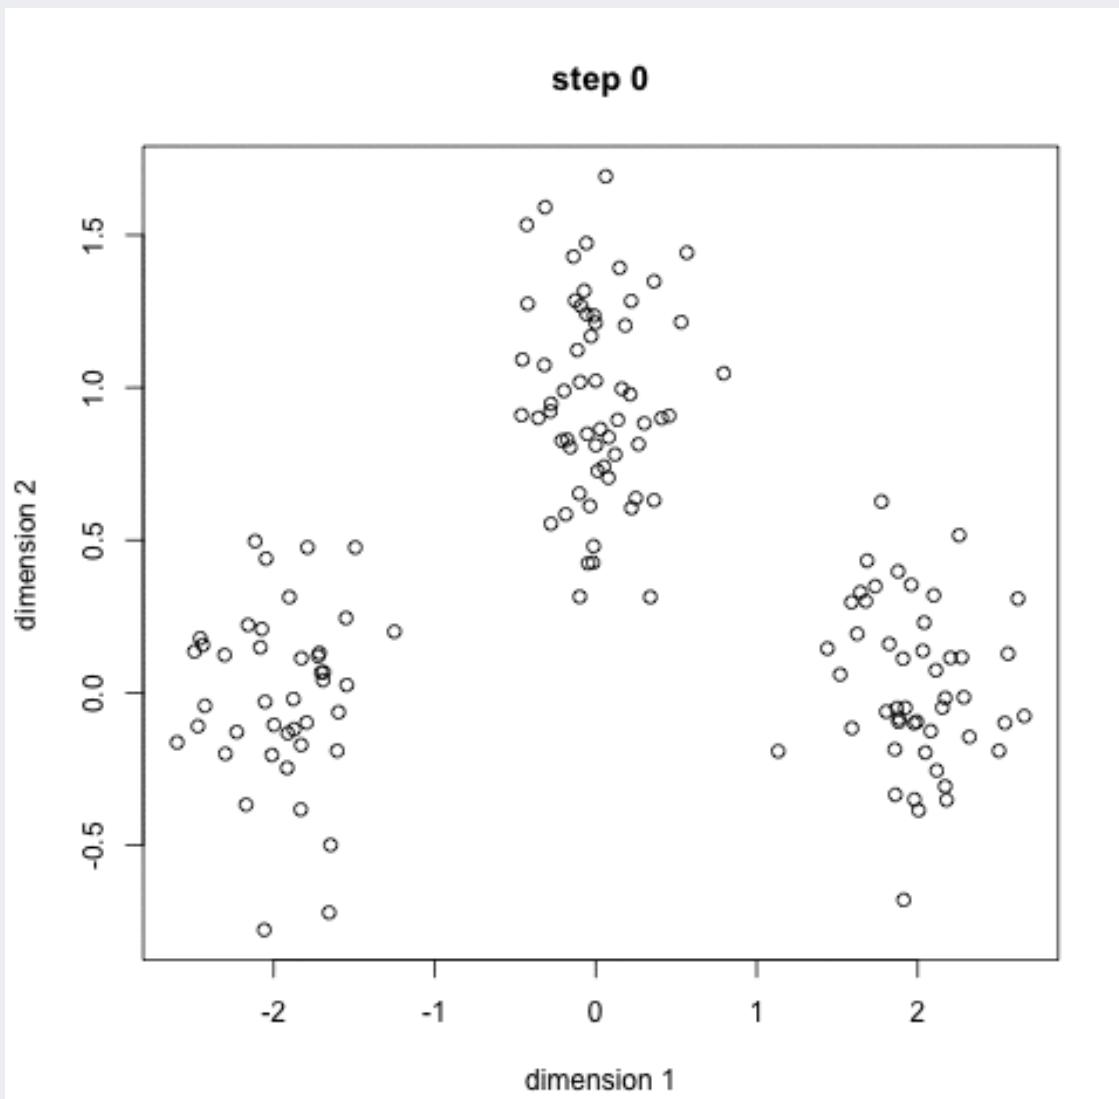

- ✓ Step 2-2 (2<sup>nd</sup> round): Re-compute the centroids with the assigned instances

- Centroids and cluster membership assignments are not changed → End the procedure

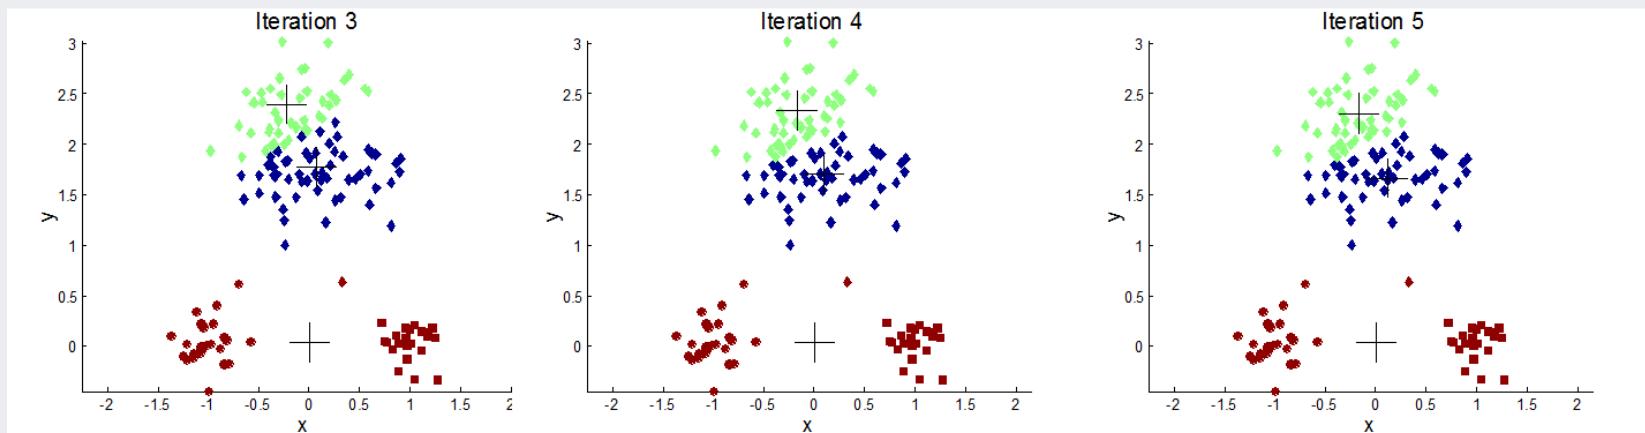

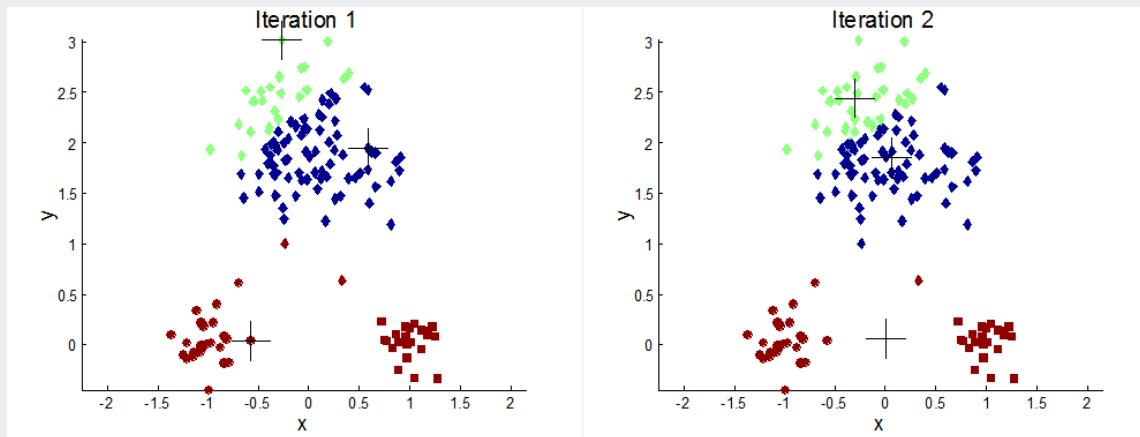

# K-Means Clustering

- KMC example

# K-Means Clustering

- Effects of initial centroids
- ✓ Undesirable centroid selection

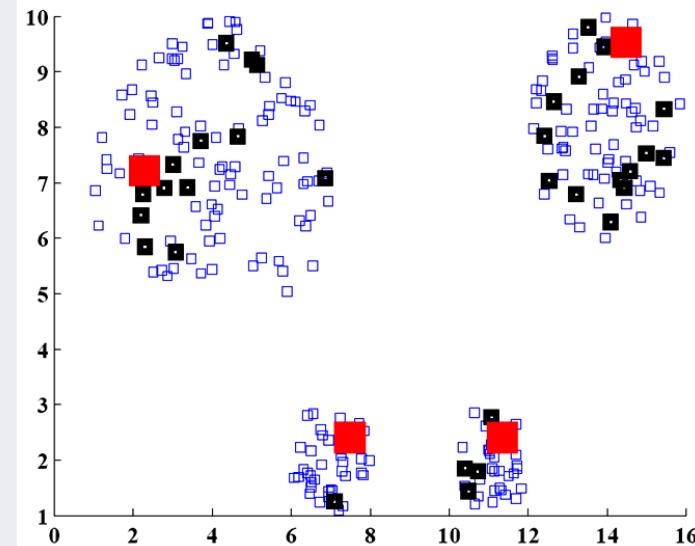

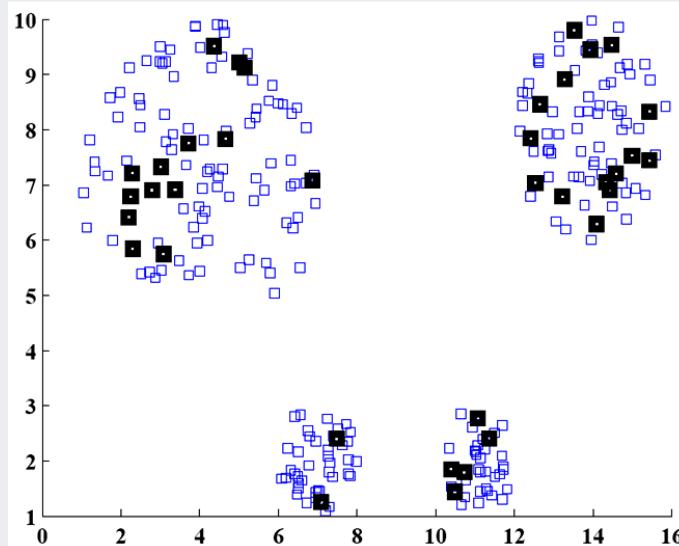

# K-Means Clustering

Kang and Cho (2009)

- Some remedies for initial centroid selection

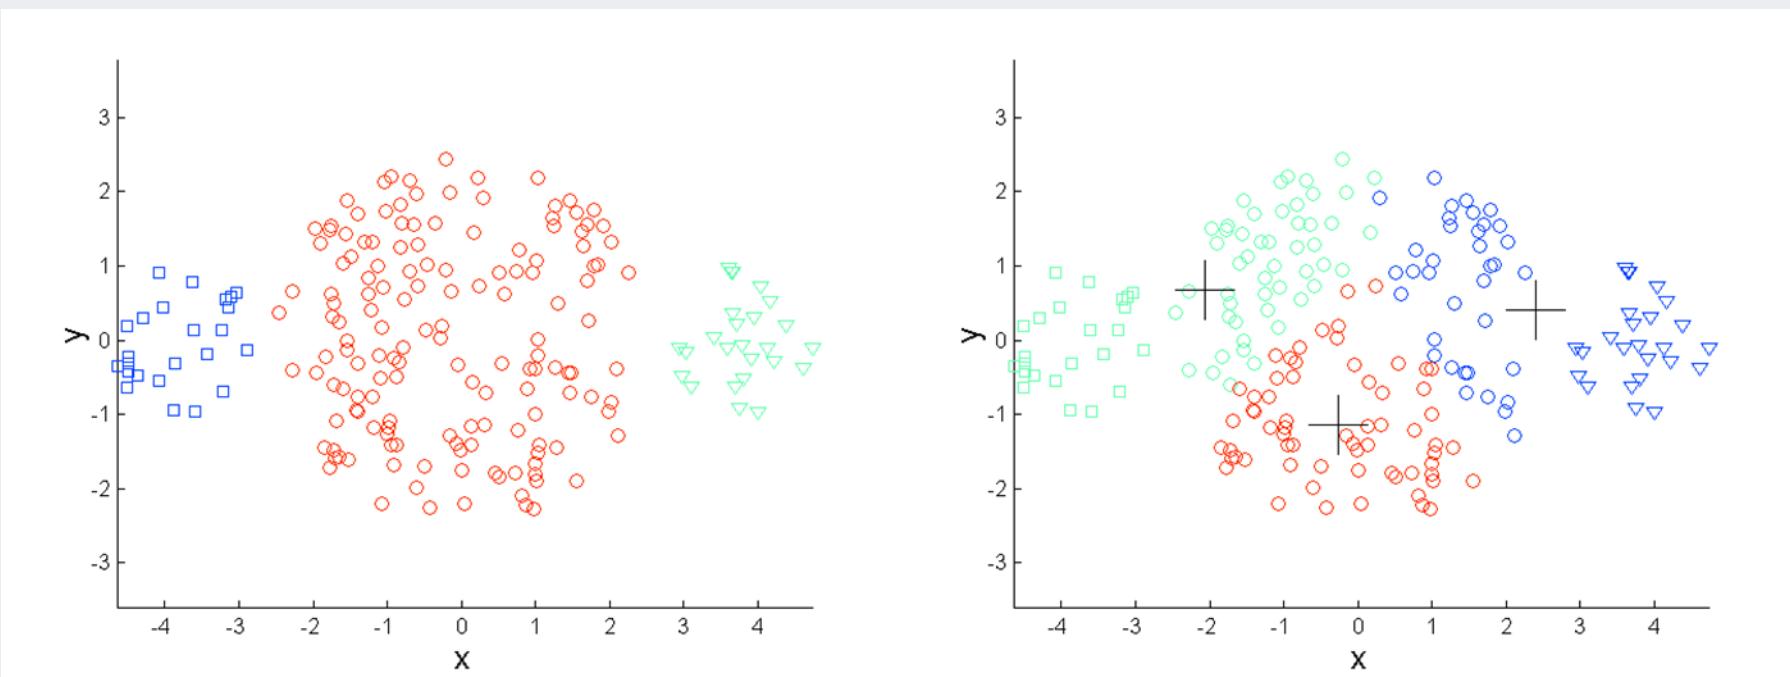

- ✓ Multiple runs
- ✓ Sample and use hierarchical clustering to determine initial centroids
- ✓ Preprocessing & Postprocessing

$$\mathcal{L}(\mathbf{x}_s | \mathbf{S}, \mathbf{C}) = d_G(\mathbf{x}_s, \mathbf{S}) \times \frac{1}{1 + \exp(-d_R(\mathbf{x}_s, \mathbf{S}))}$$

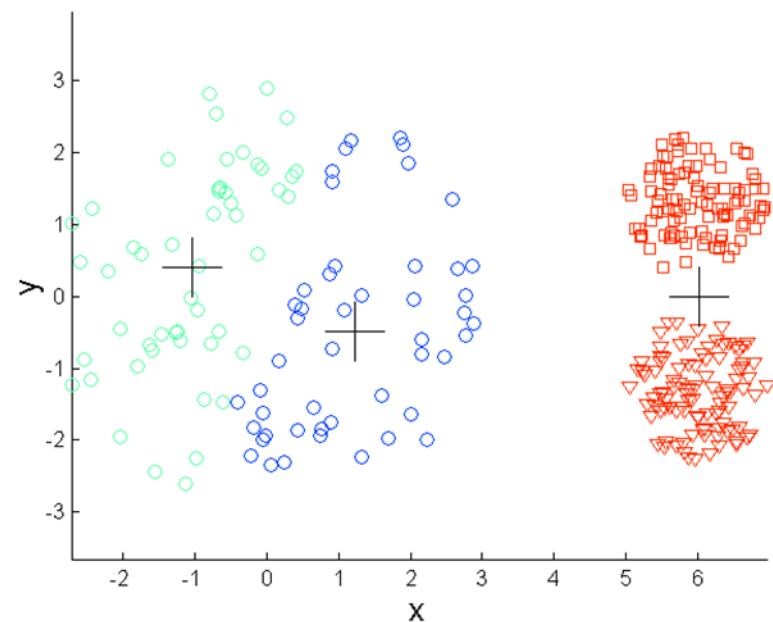

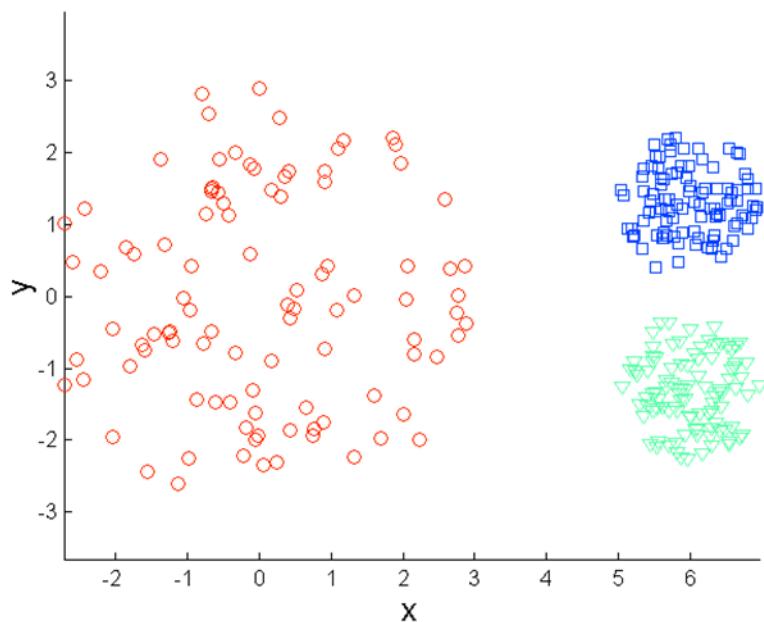

# K-Means Clustering

- Limitations of K-Means Clustering
  - ✓ Cannot cope with different sizes

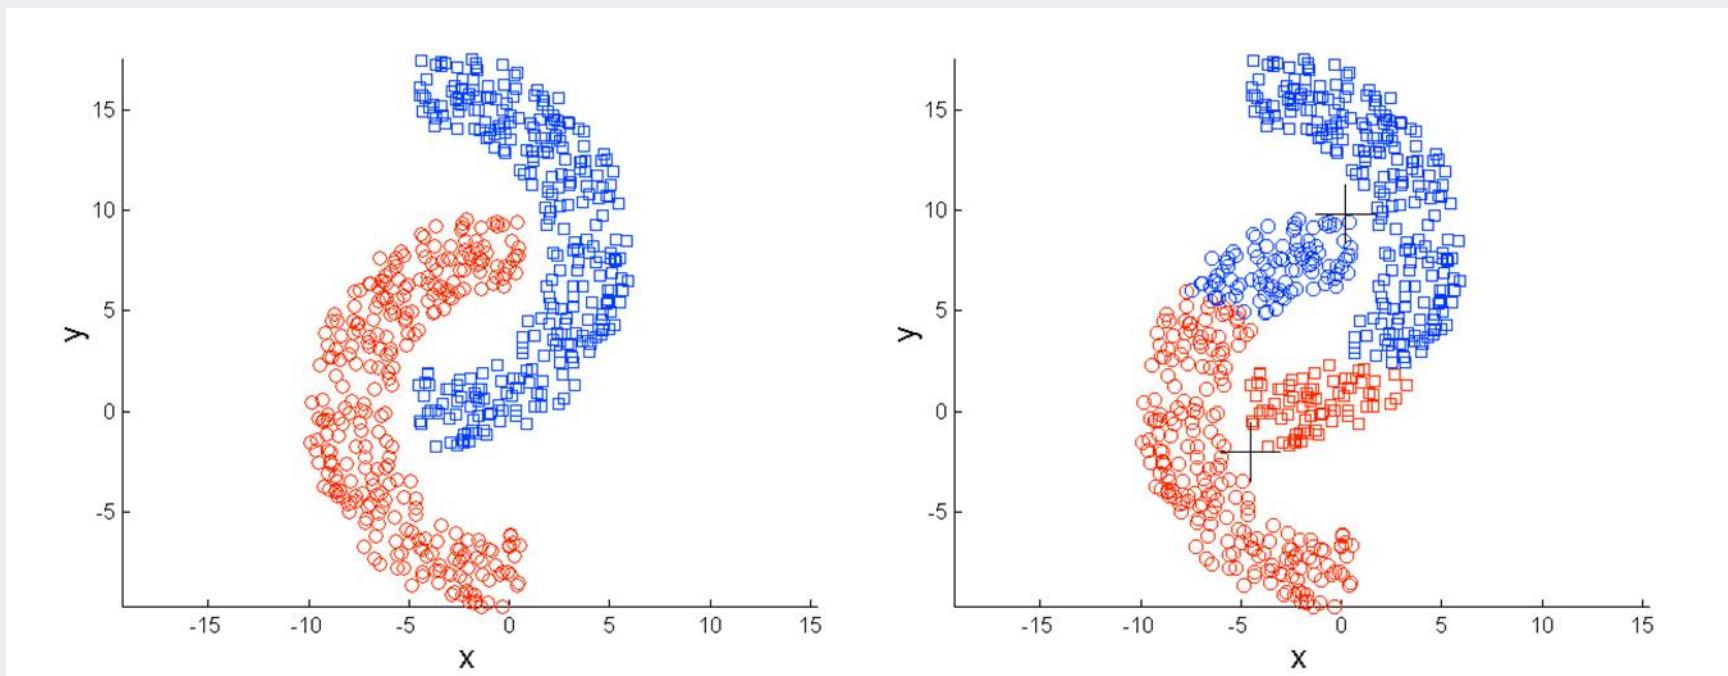

# K-Means Clustering

- Limitations of K-Means Clustering
  - ✓ Cannot cope with different densities

# K-Means Clustering

- Limitations of K-Means Clustering
  - ✓ Cannot cope with non-globular shapes

# Hierarchical Clustering

- Hierarchical clustering
  - ✓ Produces a set of nested clusters organized as a hierarchical tree
  - ✓ Can be visualized as a dendrogram
    - A tree like diagram that records the sequences of merges or splits

# Hierarchical Clustering

- Hierarchical clustering
  - ✓ Produces a set of nested clusters organized as a hierarchical tree
  - ✓ Can be visualized as a dendrogram
    - A tree like diagram that records the sequences of merges or splits

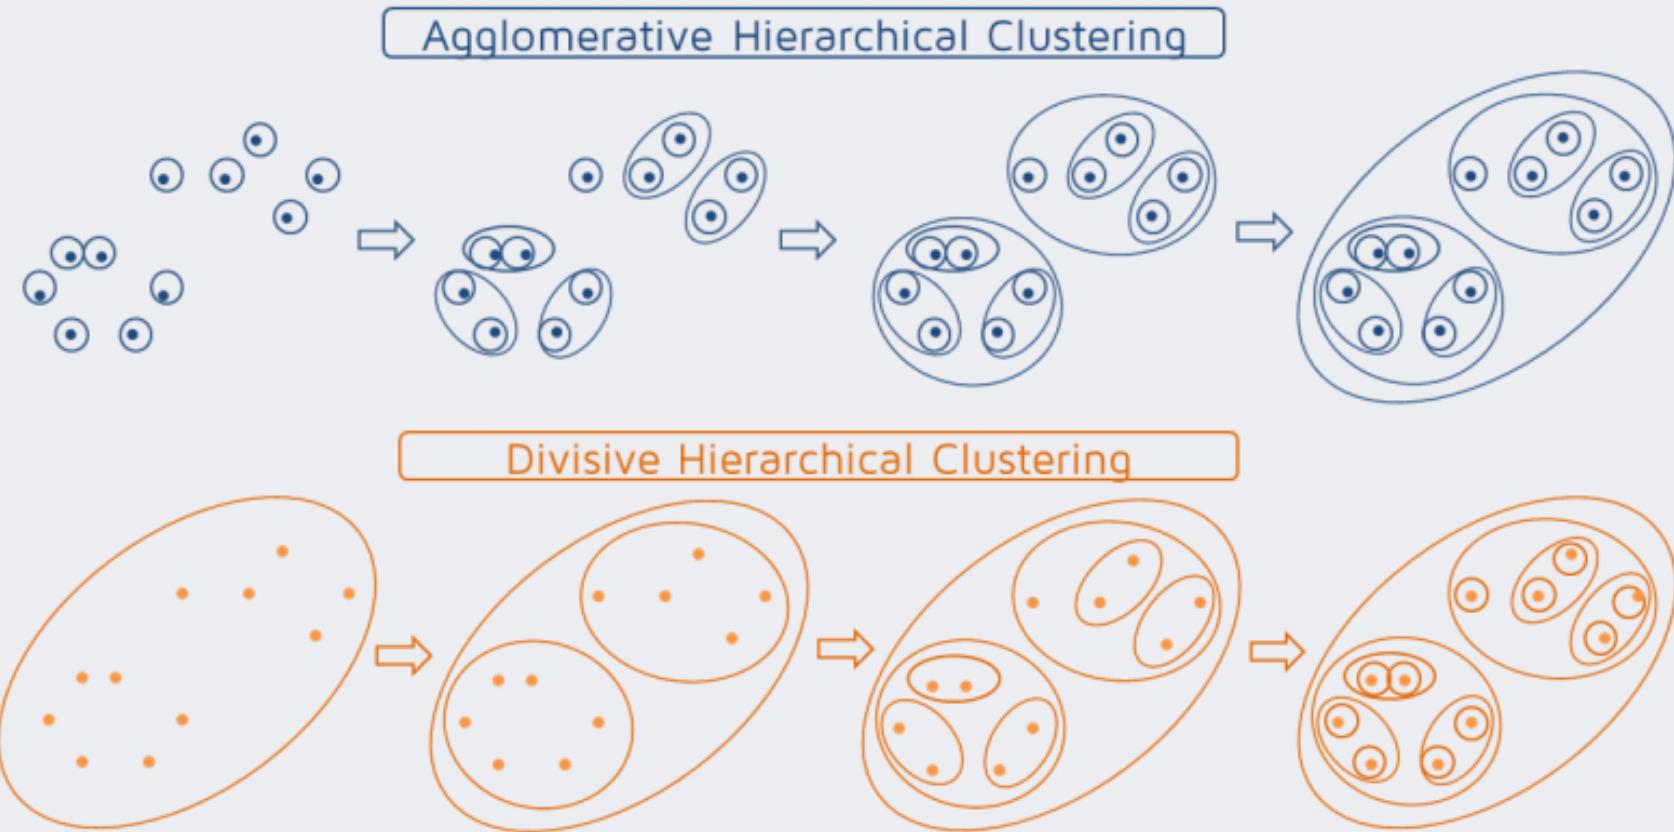

# Hierarchical Clustering

- Strengths of Hierarchical clustering
  - ✓ Do not have to assume any particular number of clusters
    - Any desired number of clusters can be obtained by ‘cutting’ the dendrogram at the proper level
  - ✓ May correspond to meaningful taxonomies
- Two main types of hierarchical clustering
  - ✓ Agglomerative clustering
    - Start with the points as individual clusters
    - At each step, merge the closest pair of clusters until only one cluster left
  - ✓ Divisive clustering
    - Start with one, all-inclusive cluster
    - At each step, split a cluster until each cluster contains a point

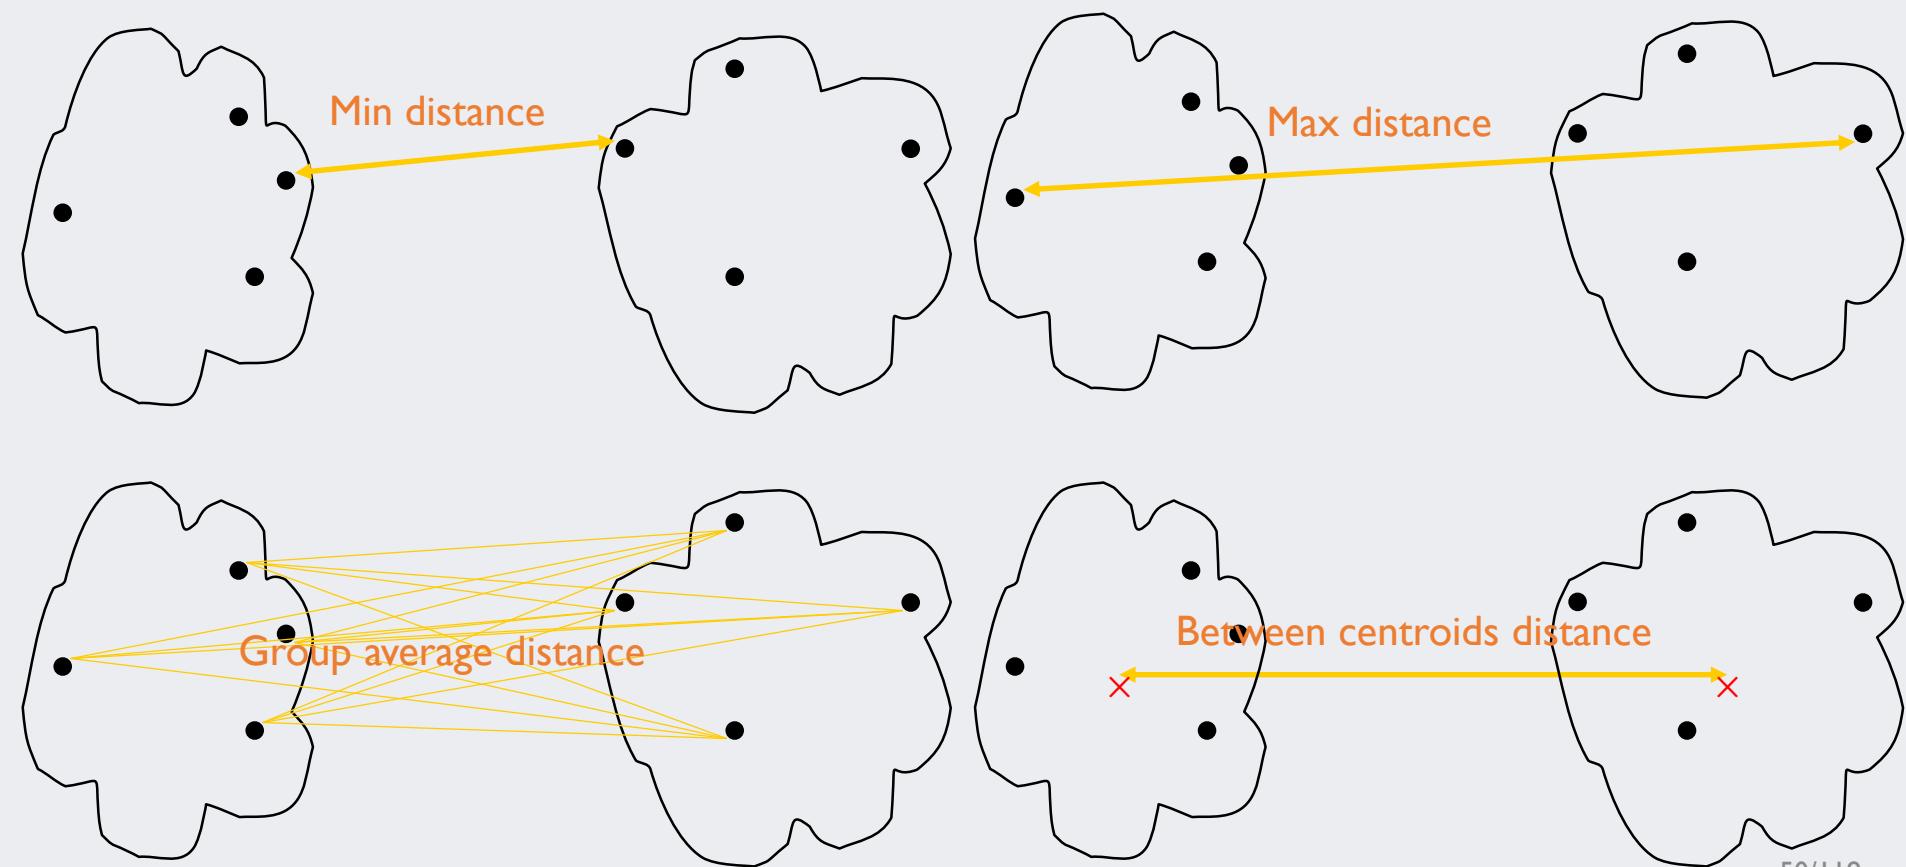

# Hierarchical Clustering

- Strengths of Hierarchical clustering
  - ✓ Agglomerative clustering vs. Divisive clustering

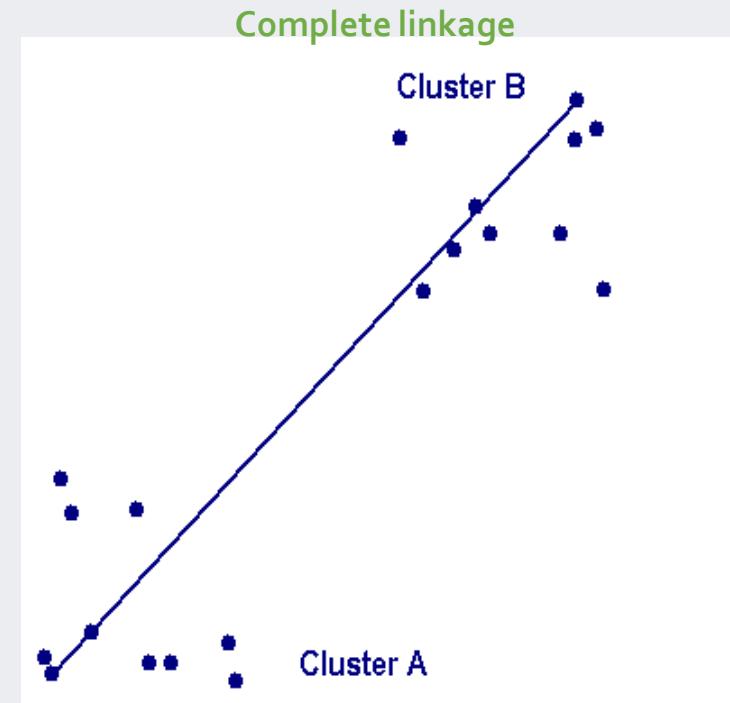

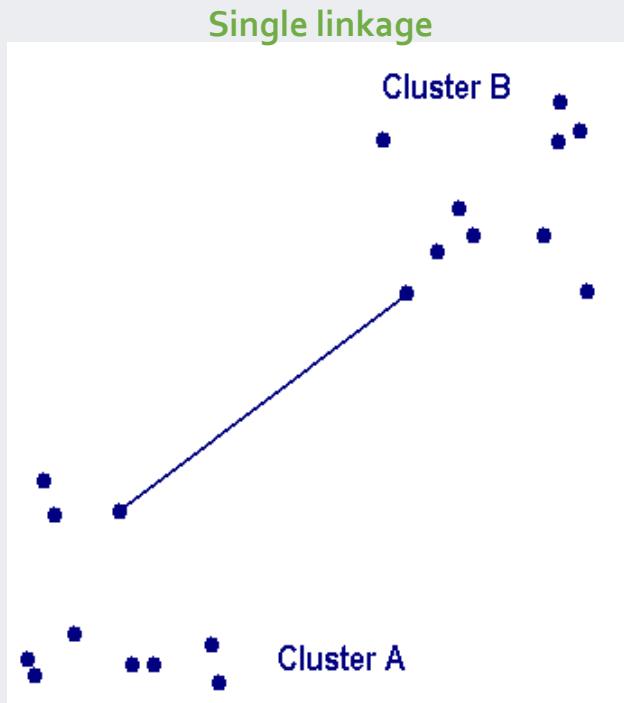

# Hierarchical Clustering

- Agglomerative clustering algorithm
  - ✓ Key operation: computation of the proximity of two clusters
    - Min, max, group average, between centroid, etc.

# Hierarchical Clustering

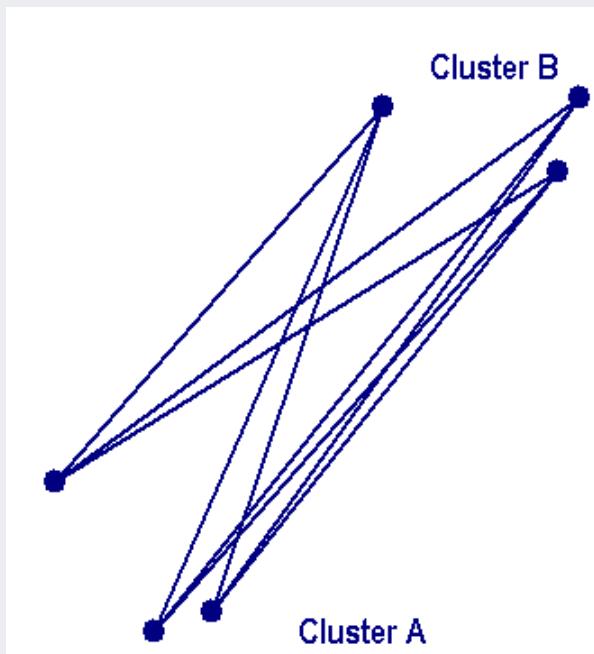

- Agglomerative clustering algorithm
  - ✓ Single linkage: minimum distance between two data points in different clusters
  - ✓ Complete linkage: maximum distance between two data points in different clusters

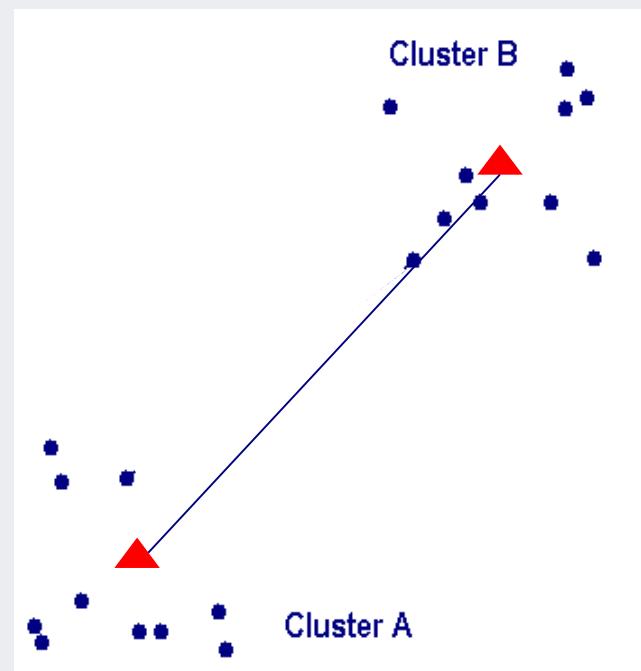

# Hierarchical Clustering

- Agglomerative clustering algorithm
  - ✓ Average linkage: mean distance between two data points in different clusters
  - ✓ Centroid linkage: distance between centroids in different clusters

Average linkage

Centroid linkage

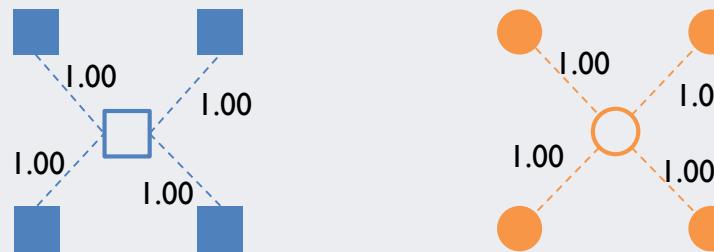

# Hierarchical Clustering

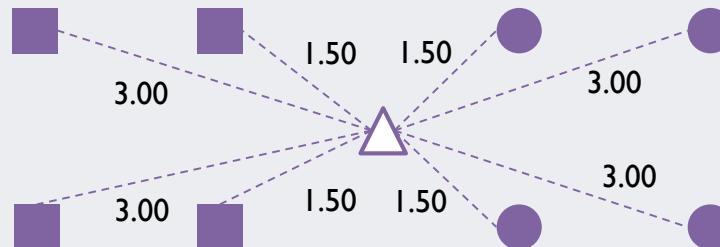

- Agglomerative clustering algorithm

✓ Ward method: Compare the sum of squared error (SSE) before and after the merge

- SSE before merge:  $1^2 + 1^2 + 1^2 + 1^2 + 1^2 + 1^2 + 1^2 + 1^2 = 8$

- SSE after merge:  $4 \times 1.5^2 + 4 \times 3^2 = 45$

- Ward distance:  $45 - 8 = 37$

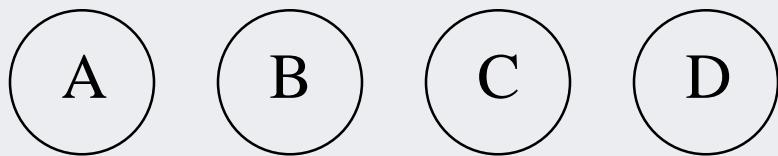

# Hierarchical Clustering

- Agglomerative clustering algorithm
  - I. Compute the proximity matrix
  - 2. Let each data point be a cluster
  - 3. Repeat**
    - I. Merge the two closest clusters
    - 2. Update the proximity matrix
  - 4. Until** only a single cluster remains

# Density-based Clustering

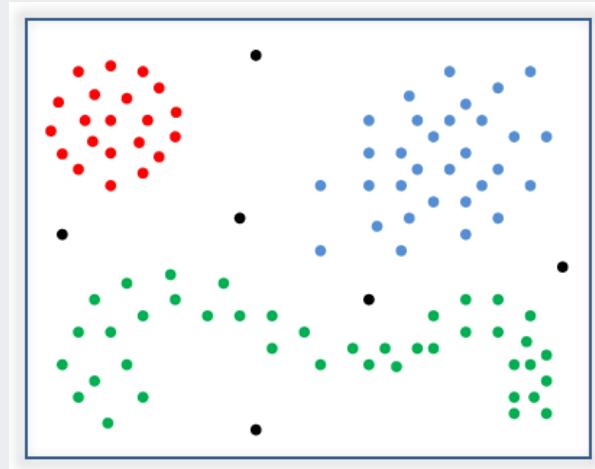

Ester et al. (1996)

- Density-based clustering
  - ✓ Conduct a clustering by considering the density of data points
    - Can find an arbitrary shape of cluster
    - Can remove noise from clustering result

# Density-based Clustering

- DBSCAN
  - ✓ Most popular density-based clustering algorithm
- Idea
  - ✓ Clusters are the collections of data points with high density
  - ✓ Density around a noise point is very low
- Purpose
  - ✓ Quantify the features of clusters and noise points to find a set of valid clusters

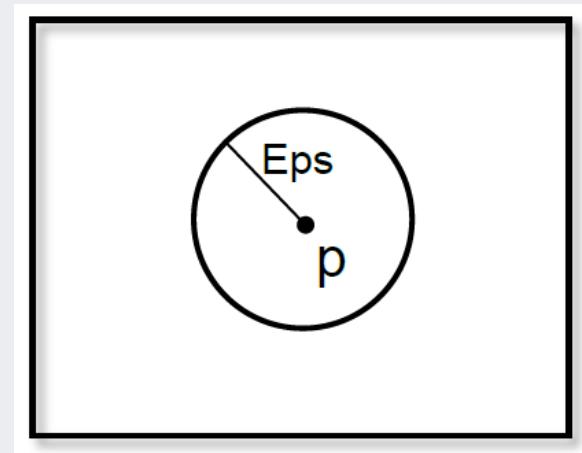

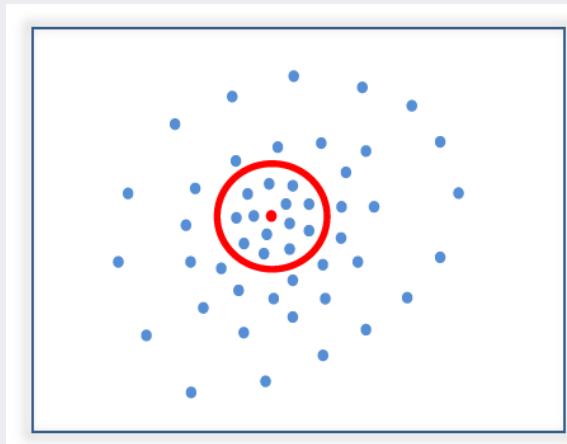

# Density-based Clustering

- DBSCAN

- ✓ **Definition 1:  $\epsilon$ -neighborhood of a point**

- The  $\epsilon$ -neighborhood of a point, denoted by  $N_\epsilon(p)$ , is defined by

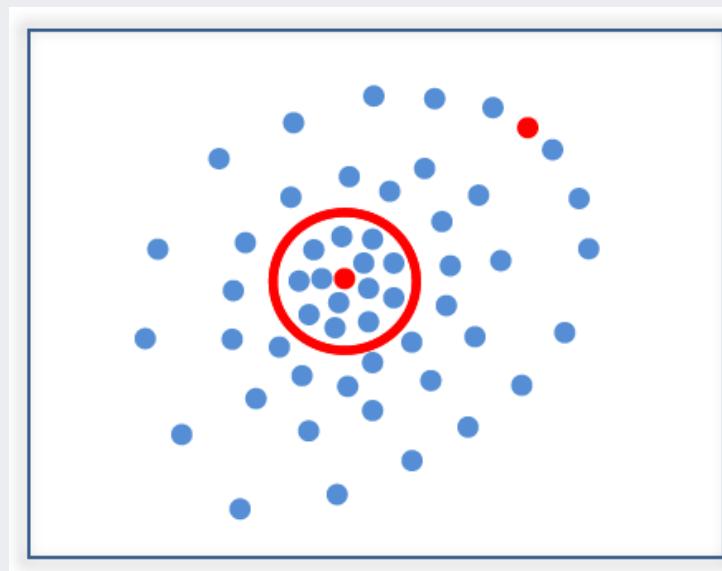

$$N_\epsilon(p) = \{q \in D \mid dist(p, q) \leq \epsilon\}$$

- ✓ **Naïve Approach:** require for each point in a cluster that there are at least a minimum number (**MinPts**) of points in an  $\epsilon$ -neighborhood of that point

# Density-based Clustering

- DBSCAN
  - ✓ Problem of Naïve Approach
    - There are two kinds of points in a cluster
      - Points inside of the cluster (core points)
      - Points on the border of the cluster (border points)
    - An  $\epsilon$ -neighborhood of a border point contains significantly less points than an  $\epsilon$ -neighborhood of a core point

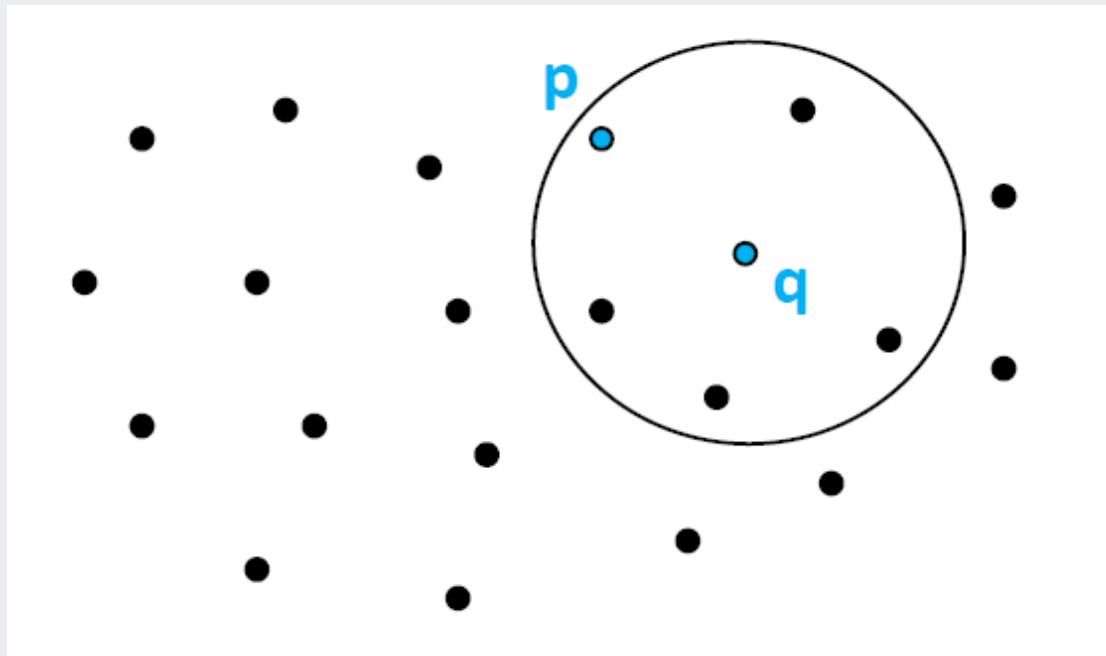

# Density-based Clustering

- DBSCAN

- ✓ Better idea

- For every point  $p$  in a cluster  $C$ , there is a point  $q$  in  $C$  so that  $p$  is inside of the  $\epsilon$ -neighborhood of  $q$  (Border points are connected to core points)
  - $N_\epsilon(q)$  contains at least MinPts points (Core points = high density)

# Density-based Clustering

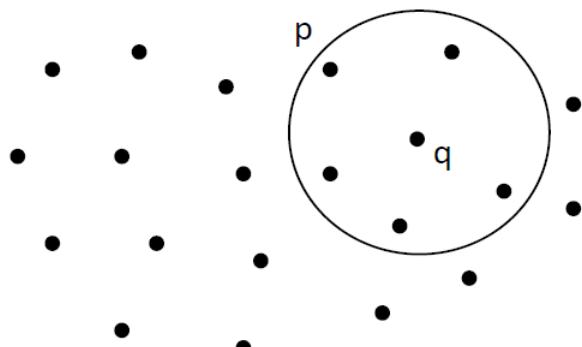

- DBSCAN

✓ **Definition 2: directly density-reachable**

- A point  $p$  is directly density-reachable from a point  $q$  with regard to the parameters  $\epsilon$  and  $\text{MinPts}$ , if

1)  $p \in N_\epsilon(q)$  (*reachability*)

2)  $|N_\epsilon(q)| \geq \text{MinPts}$  (*core point condition*)

$$\text{MinPts} = 5$$

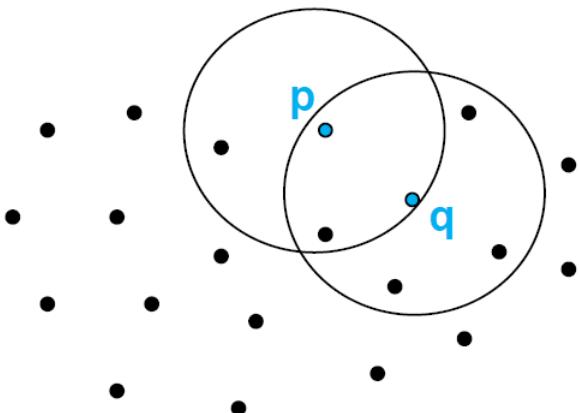

$$|N_{\epsilon}(q)| = 6 \geq 5 = \text{MinPts} \text{ (core point condition)}$$

# Density-based Clustering

- DBSCAN

- ✓ Property

- Directly density-reachable is symmetric for pairs of core points
    - It is not symmetric if one core point and one border point are involved

Parameter: MinPts = 5

p directly density reachable from q

$$p \in N_{Eps}(q)$$

$|N_{Eps}(q)| = 6 \geq 5 = \text{MinPts}$  (core point condition)

q not directly density reachable from p

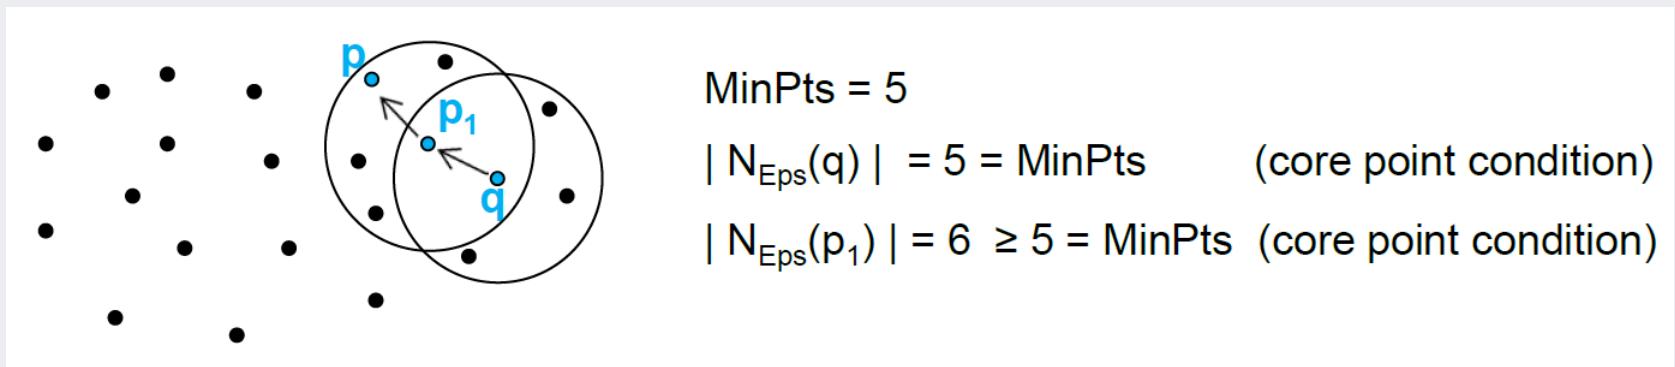

$|N_{Eps}(p)| = 4 < 5 = \text{MinPts}$  (core point condition)

# Density-based Clustering

- DBSCAN

- ✓ **Definition 3: density-reachable**

- A point  $p$  is density-reachable from a point  $q$  with regard to the parameters  $\epsilon$  and MinPts, if there is a chain of points  $p_1, p_2, \dots, p_s$  with  $p_1 = q$  and  $p_s = p$  such that  $p_{i+1}$  is directly density-reachable from  $p_i$  for all  $1 < i < s-1$

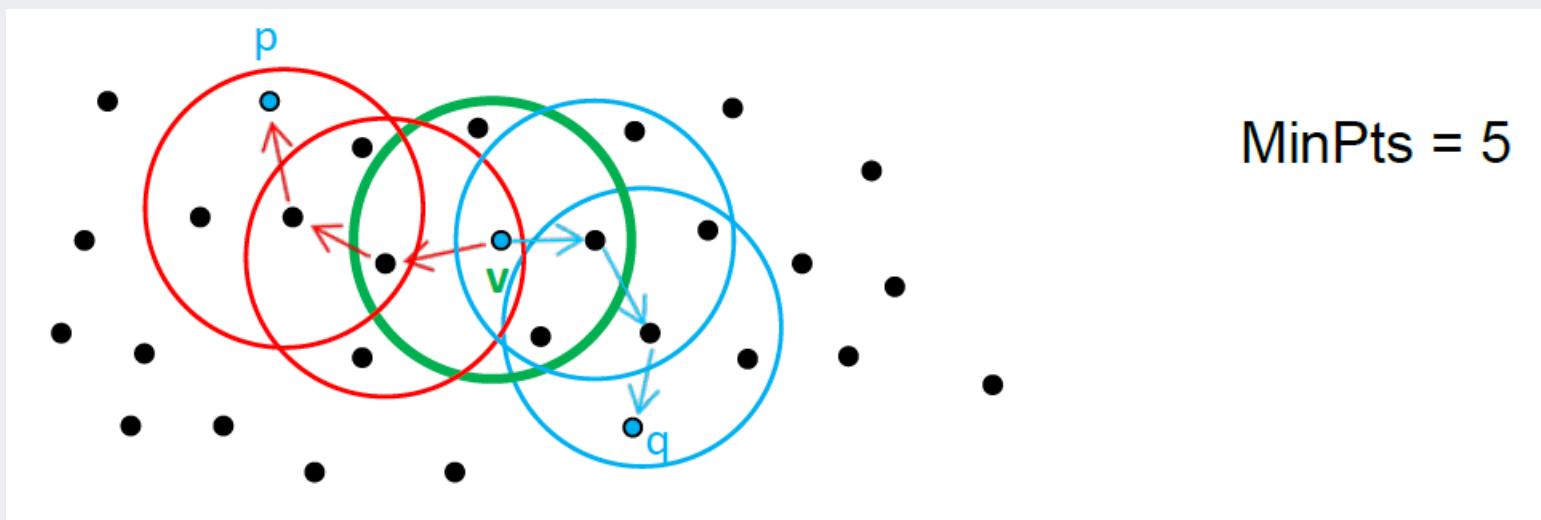

# Density-based Clustering

- DBSCAN

- ✓ **Definition 4: density-connected**

- A point  $p$  is density-connected to a point  $q$  with regard to the parameters  $\varepsilon$  and  $\text{MinPts}$ , if there is a point  $v$  such that both  $p$  and  $q$  are density-reachable from  $v$

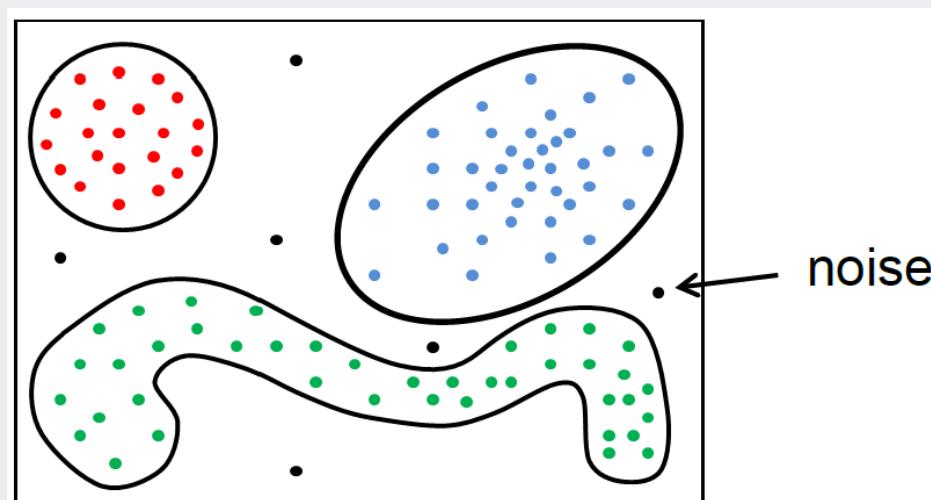

# Density-based Clustering

- DBSCAN

- ✓ **Definition 5: Cluster**

- A cluster with regard to the parameters  $\varepsilon$  and MinPts is a non-empty subset  $C$  of the database  $D$  with
      - (1) For all  $p, q \in D$ : If  $p \in C$  and  $q$  is density-reachable from  $p$  with regard to the parameters  $\varepsilon$  and MinPts, then  $q \in C$  (**Maximality**)
      - (2) For all  $p, q \in C$ : The point  $p$  is density-connected to  $q$  with regard to the parameters  $\varepsilon$  and MinPts (**Connectivity**)

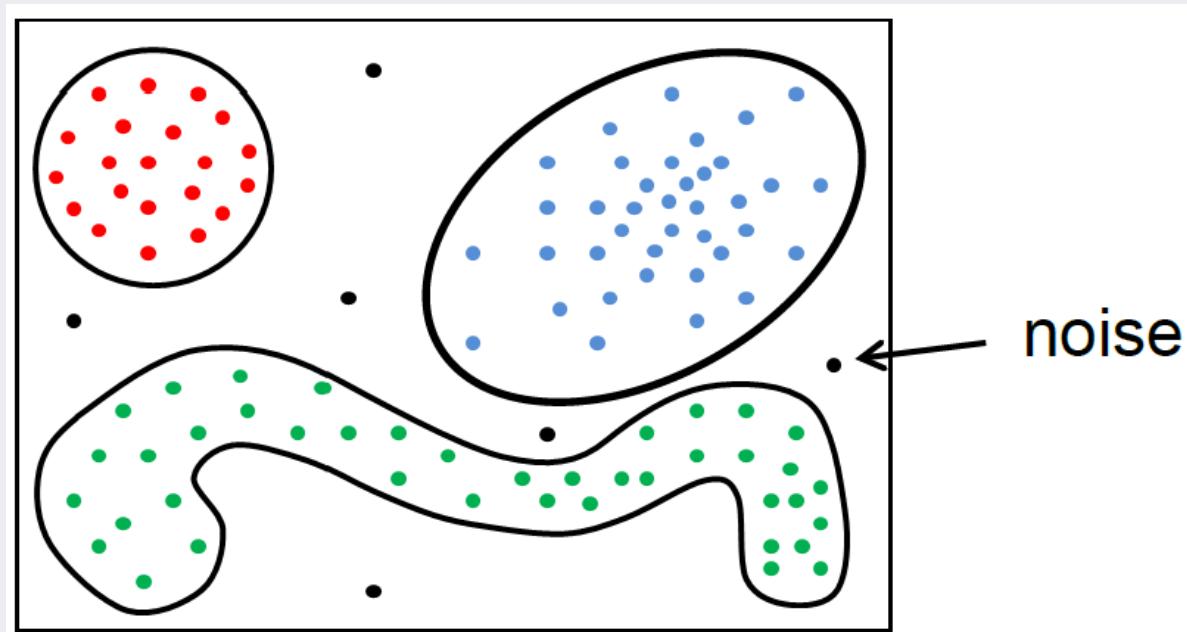

# Density-based Clustering

- DBSCAN

✓ **Definition 6: Noise**

- Let  $C_1, \dots, C_k$  be the clusters of the database D with regard to the parameters  $\varepsilon$  and MinPts
- The set of points in the database D not belonging to any cluster  $C_1, \dots, C_k$  is called noise

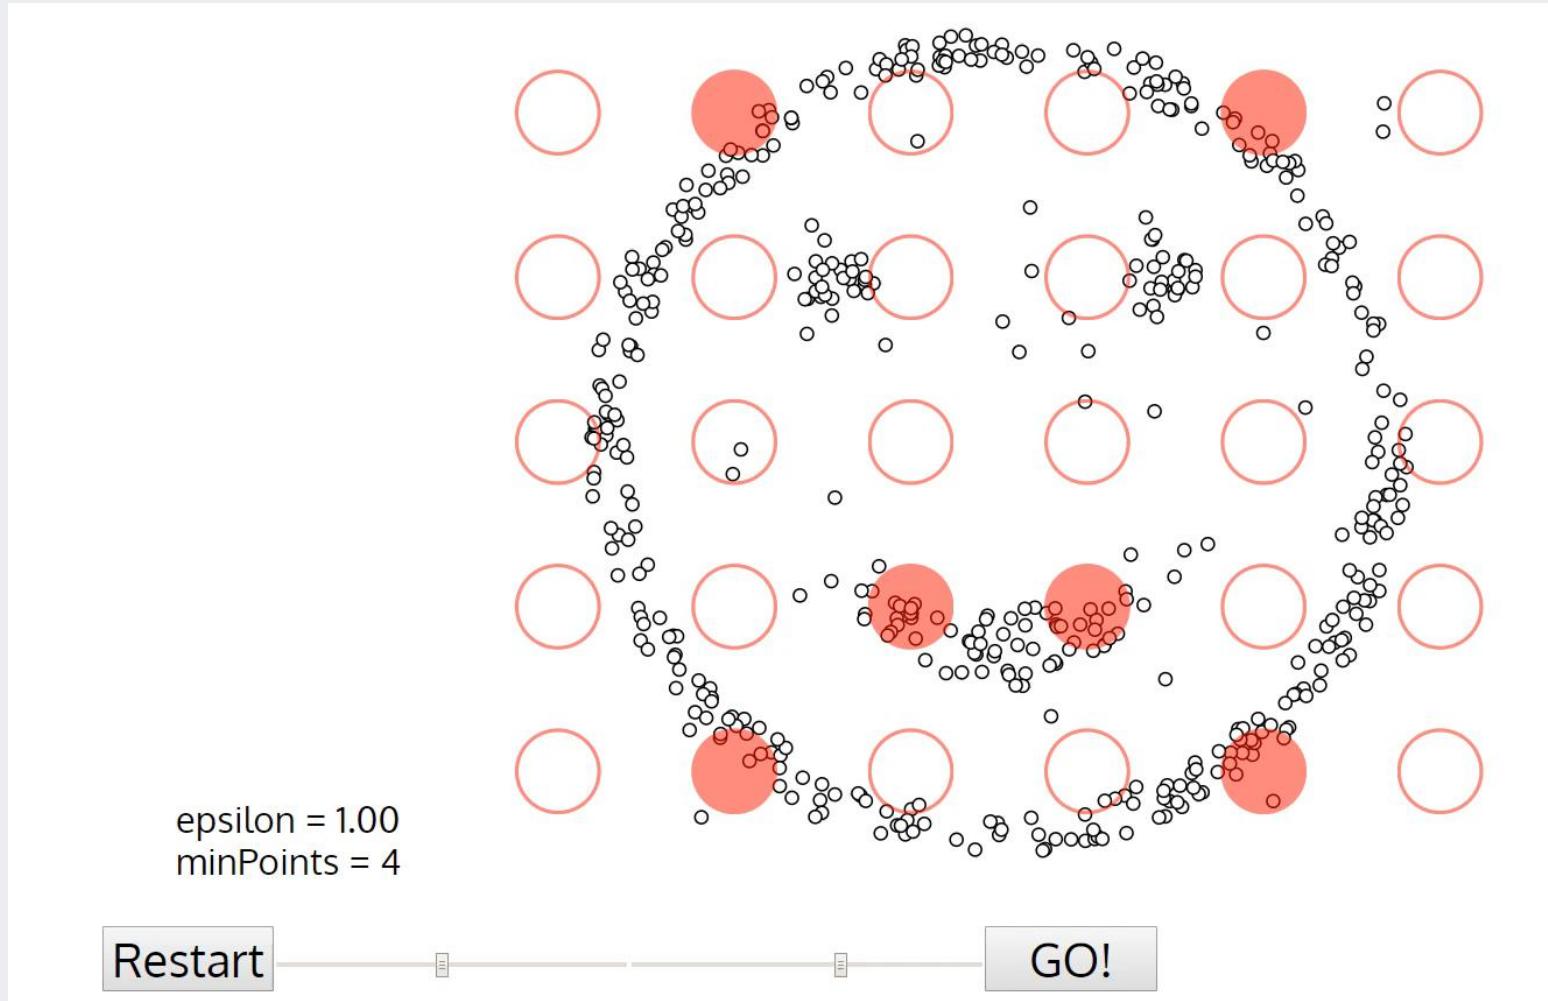

# Density-based Clustering

- DBSCAN:Algorithm
  - ✓ Input: N objects to be clustered and global parameter,  $\varepsilon$  and MinPts
  - ✓ Output: Cluster of objects
- Algorithm
  - ✓ Arbitrary select a point p
  - ✓ Retrieve all points density-reachable from p w.r.t.  $\varepsilon$  and MinPts
  - ✓ If p is a core points, a cluster is formed
  - ✓ If p is a border point, no points are density reachable from p and DBSCAN visits the next point of the database
  - ✓ Continue the process until all of the points have been processed

# Spectral Clustering

- Spectral Clustering

- ✓ Treats the data as a graph partitioning problem without make any assumption on the form of the data clusters
  - Easy to implement
  - Reasonably fast especially for sparse data sets up to several thousands

# Spectral Clustering

- Graph theory view of clustering
  - ✓ The database is composed of  $n$  points
  - ✓ All points are characterized by their pair-wise similarities
    - Each pair of points  $(x_i, x_j)$  is associated a similarity value  $w_{ij}$ , and the similarity matrix  $W$  in  $\mathbb{R}^{n \times n}$  is composed of terms  $w_{ij}$  which can be of (Cosine or Gaussian type)
    - Gaussian kernel is commonly used in spectral clustering

$$w_{ij} = \exp\left(-\frac{\|x_i - x_j\|^2}{2\sigma^2}\right)$$

# Spectral Clustering

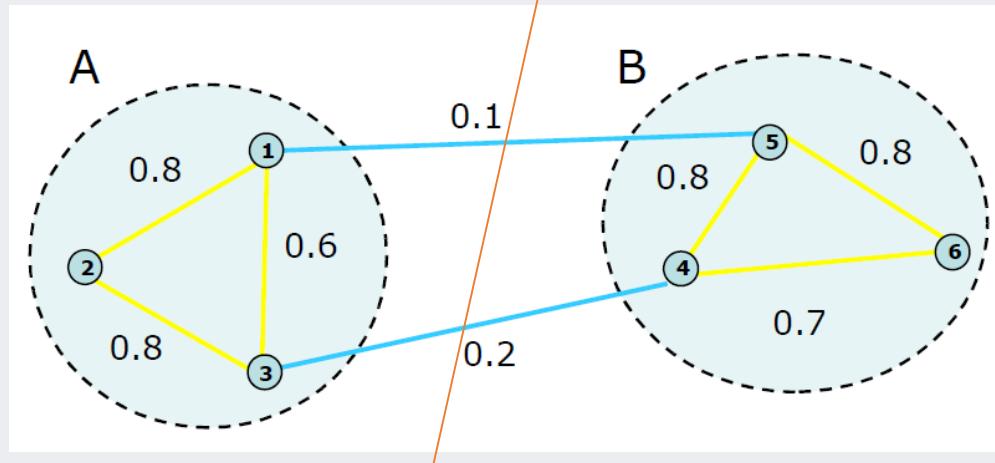

- Graph construction
  - ✓ Fully connected graph
    - All vertices having non-null similarities are connected each other
  - ✓  $\varepsilon$ -neighborhood graph
    - Each vertex is connected to vertices falling inside a ball of radius  $\varepsilon$  where  $\varepsilon$  is a real value that has to be tuned in order to catch the local structure of data
  - ✓ k-nearest neighbor graph
    - Each vertex is connected to its k-nearest neighbors where k is an integer number which controls the local relationship of data
  - ✓  $\varepsilon$ -neighborhood and k-nearest neighbor combined

# Spectral Clustering

- Graph Cut
  - ✓ Wish to partition the graph  $G(V, E)$  into two disjoint sets of connected vertices A and B by removing edges connecting two parts
  - ✓ In graph theory, there are different objective functions: MinCut, RatioCut, Ncut, MinMaxCut, etc.
  - ✓ Given two disjoint clusters (subgraphs) A and B of the Graph G, the following three terms can be defined
    - The sum of weight connections between two clusters:
$$Cut(A, B) = \sum_{i \in A, j \in B} w_{ij}$$
    - The sum of weight connections within a single cluster (e.g., A):
$$Cut(A, A) = \sum_{i \in A, j \in A} w_{ij}$$
    - The total weights of edges originating from a cluster (e.g., A)
$$Vol(A) = \sum_{i \in A} \sum_j w_{ij}$$

# Spectral Clustering

- Graph Cut: Illustrative example

$$Cut(A, B) = \sum_{i \in A, j \in B} w_{ij} = 0.3$$

$$Cut(A, A) = \sum_{i \in A, j \in A} w_{ij} = 2.2$$

$$Cut(B, B) = \sum_{i \in B, j \in B} w_{ij} = 2.3$$

$$Vol(A) = \sum_{i \in A} \sum_j w_{ij} = 4.7$$

$$Vol(A) = \sum_{i \in A} \sum_j w_{ij} = 4.9$$

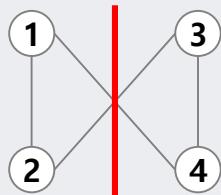

# Spectral Clustering

- Graph Cut: Minimum cut method
  - ✓ Find two clusters A and B which have the minimum weight sum connections
  - Objective function

$$\text{MinCut}(A, B) = \text{Min } \frac{1}{4} q^T (D - W) q$$

$$D_{ii} = \sum_j w_{ij}, D_{ij} = 0 \text{ if } i \neq j \quad q_i = 1 (i \in A), -1 (i \in B)$$

- Example

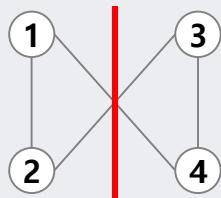

$$\begin{aligned} (D - W)q &= \begin{bmatrix} w_{12} + w_{14} & -w_{12} & 0 & -w_{14} \\ -w_{21} & w_{21} + w_{23} & -w_{23} & 0 \\ 0 & -w_{32} & w_{32} + w_{34} & -w_{34} \\ -w_{41} & 0 & -w_{43} & w_{41} + w_{43} \end{bmatrix} \begin{bmatrix} 1 \\ 1 \\ -1 \\ -1 \end{bmatrix} \\ &= \begin{bmatrix} 2w_{14} \\ 2w_{23} \\ -2w_{32} \\ -2w_{41} \end{bmatrix} \end{aligned}$$

# Spectral Clustering

- Graph Cut: Minimum cut method

- ✓ Find two clusters A and B which have the minimum weight sum connections
  - Example (cont')

$$(D - W)q = \begin{bmatrix} w_{12} + w_{14} & -w_{12} & 0 & -w_{14} \\ -w_{21} & w_{21} + w_{23} & -w_{23} & 0 \\ 0 & -w_{32} & w_{32} + w_{34} & -w_{34} \\ -w_{41} & 0 & -w_{43} & w_{41} + w_{43} \end{bmatrix} \begin{bmatrix} 1 \\ 1 \\ -1 \\ -1 \end{bmatrix}$$
$$= \begin{bmatrix} 2w_{14} \\ 2w_{23} \\ -2w_{32} \\ -2w_{41} \end{bmatrix}$$

$$\frac{1}{4} q^T (D - W)q = \frac{1}{4} [1 \ 1 \ -1 \ -1] \begin{bmatrix} 2w_{14} \\ 2w_{23} \\ -2w_{32} \\ -2w_{41} \end{bmatrix} = w_{14} + w_{23}$$

# Spectral Clustering

- Graph Cut: Minimum cut method
  - ✓ Find two clusters A and B which have the minimum weight sum connections
    - Optimization problem

$$\begin{aligned} \text{MinCut}(A, B) &= \frac{1}{4} q^T (D - W) q \\ \text{s.t. } q^T q &= |V| \end{aligned}$$

- ✓ By taking the Lagrangian multiplier

$$(D - W)q = \lambda q \rightarrow Lq = \lambda q$$

- L: Laplacian matrix (D-W)
- ✓ We will obtain the minimum cut with the second smallest eigenvector (a.k.a Fiedler vector)
  - Trivial solution: the smallest eigenvector is 0 and every element in q is also 0.

# Spectral Clustering

- Graph Cut: Ratio Cut

- ✓ Consider the size of clusters to have balanced clusters

- Optimization problem

$$RatioCut(A, B) = Min\ Cut(A, B) \left( \frac{1}{|A|} + \frac{1}{|B|} \right)$$

- MinMaxCut

- ✓ Consider the two objective functions simultaneously

- 1<sup>st</sup>: Inter-connection ( $Cut(A, B)$ ) should be minimized
    - 2<sup>nd</sup>: Intra-connection ( $Cut(A, A), Cut(B, B)$ ) should be maximized

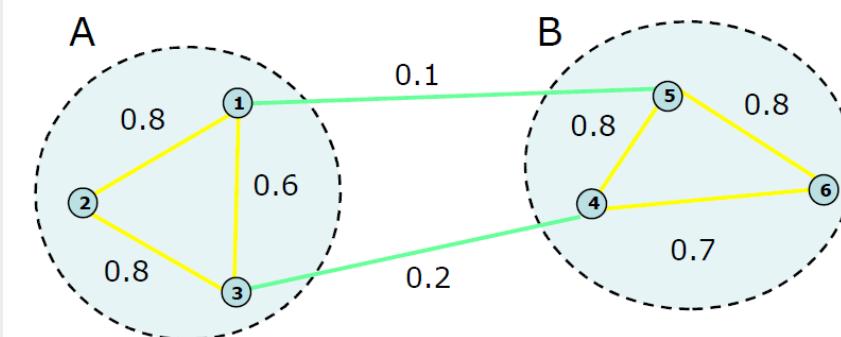

$$MinMaxCut(A, B) = Min\ Cut(A, B) \left( \frac{1}{Cut(A, A)} + \frac{1}{Cut(B, B)} \right)$$

# Spectral Clustering

- Preprocessing
  - ✓ Construct the graph and the similarity matrix representing the dataset
- Spectral Representation
  - ✓ Form the associated Laplacian matrix
  - ✓ Compute eigenvalues and eigenvectors of the Laplacian matrix
  - ✓ Map each point to a lower-dimensional representation based on one or more eigenvectors
- Clustering
  - ✓ Assign points to two or more classes, based on the new representation

# Spectral Clustering

# Self-Organizing Map (SOM)

- Self-Organizing Map (SOM)

- ✓ A way to represent higher dimensional data in an 2-D or 3-D grid such that similar records are grouped together

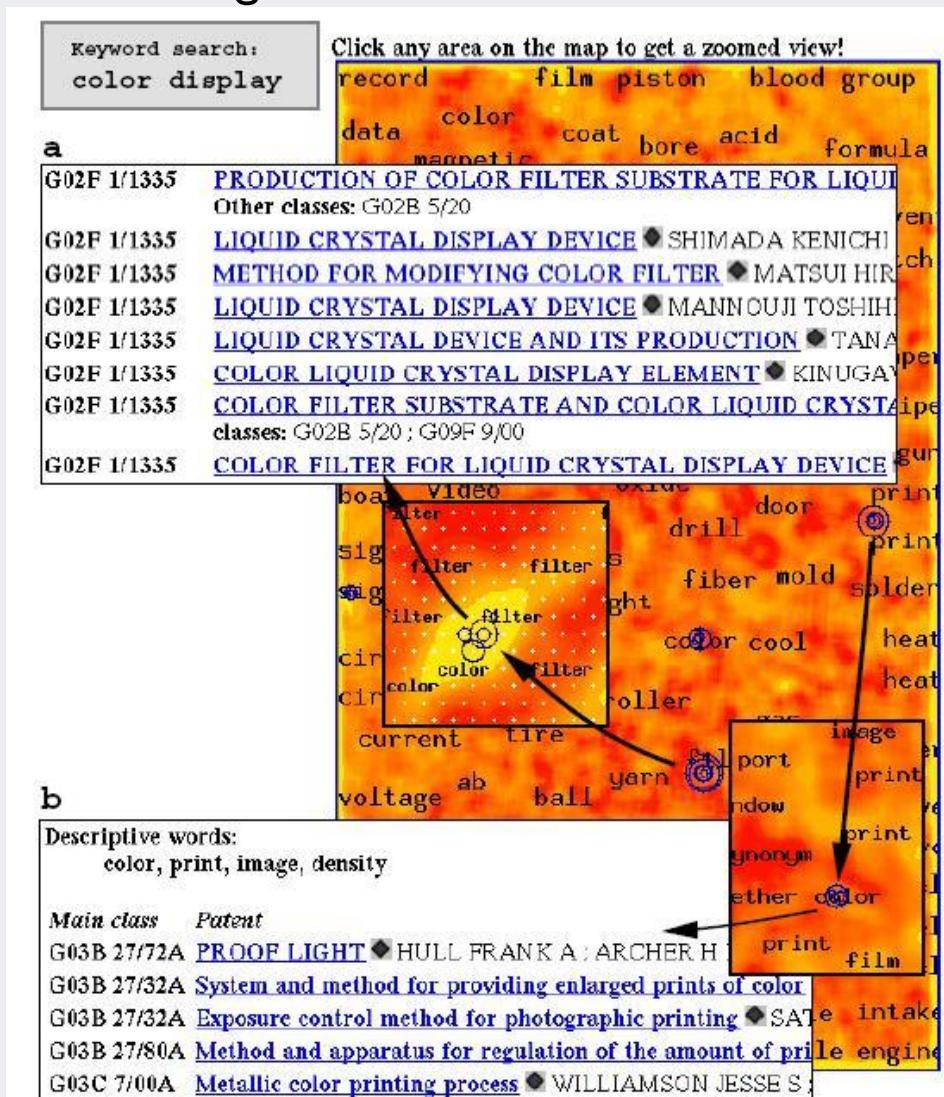

- Idea first introduced by C. von der Malsburg (1973), developed and refined by T. Kohonen (1982)
- Neural network algorithm using unsupervised competitive learning

- ✓ Geometric relationships between image points indicate similarity

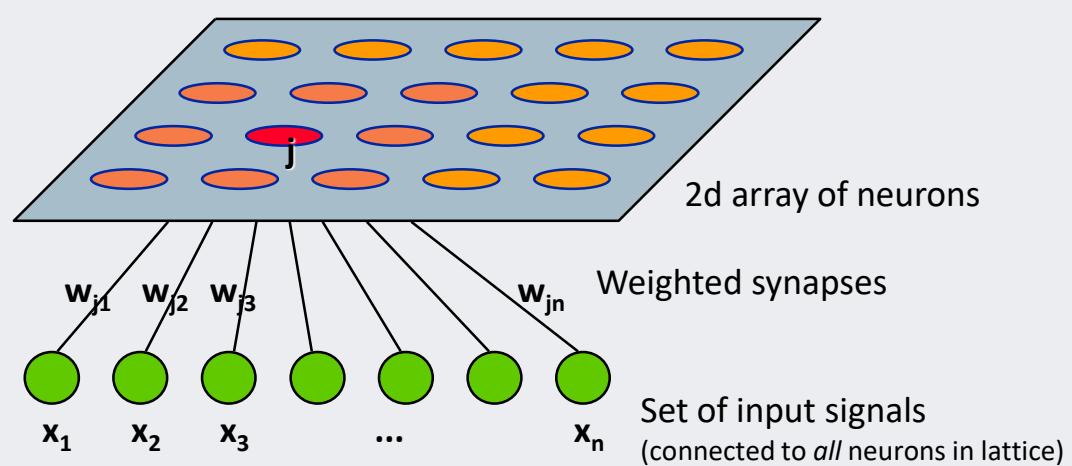

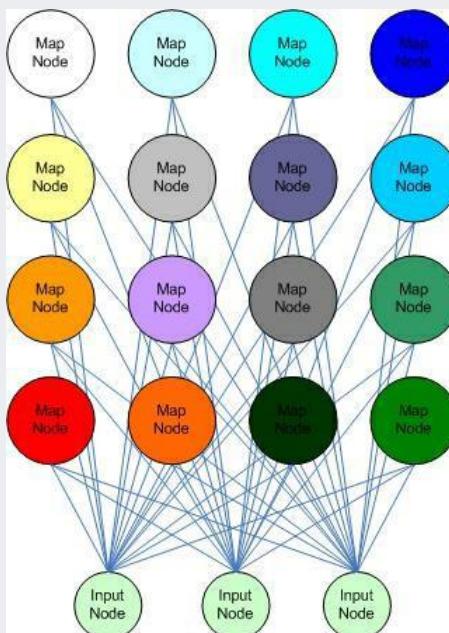

# Self-Organizing Map (SOM)

- Application: Document Organization

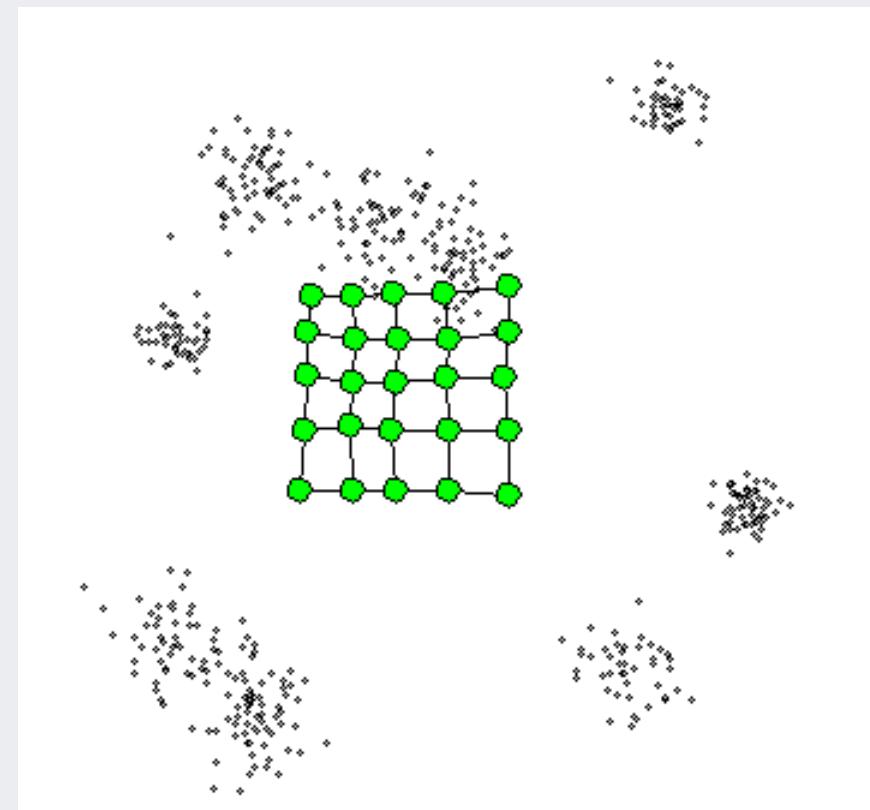

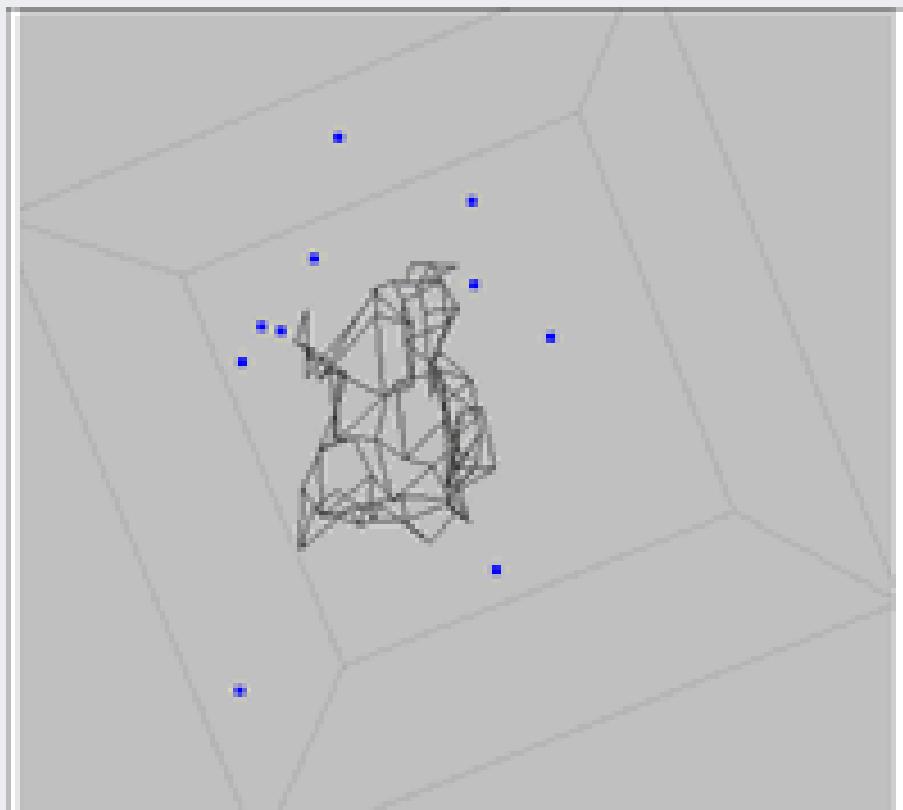

# Self-Organizing Map (SOM)

- SOM: Architecture
  - ✓ Every node (lattice of neurons) is connected to every input data in the same way, and no nodes are connected to each other.
  - ✓ Responses from the input is compared and ‘winning’ node is selected
  - ✓ Selected node is activated together with ‘neighborhood’ node
  - ✓ Adaptive process changes weights to more closely resemble inputs

# Self-Organizing Map (SOM)

- SOM: Architecture

# Self-Organizing Map (SOM)

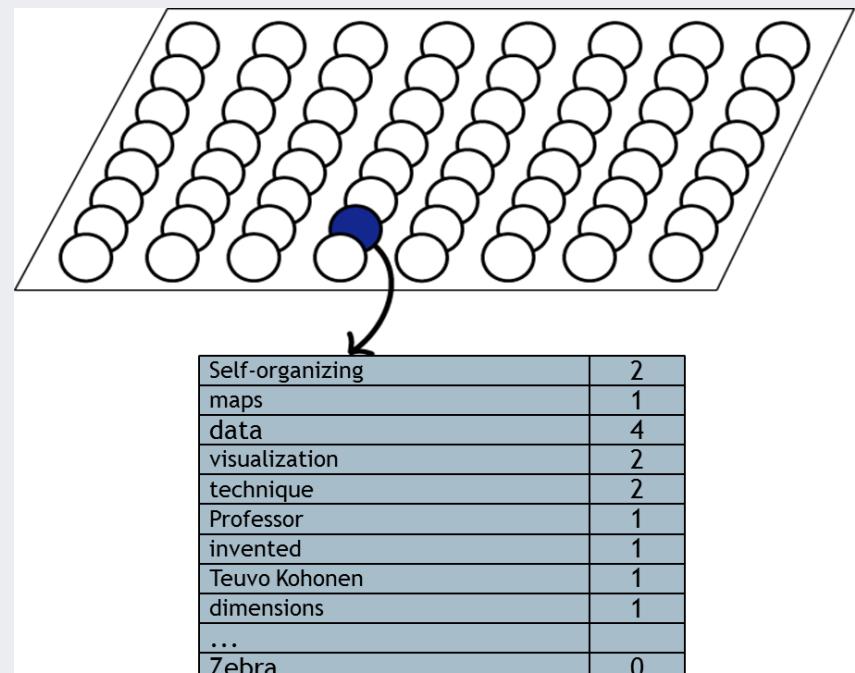

- SOM: Learning
  1. Initialize each node's weights (usually at random)
  2. Choose a random vector from training data and present it to the SOM
  3. Every node is examined to find the **Best Machine Unit (BMU)**
  4. The radius of the neighborhood around the BMU is calculated, the size of the neighborhood decreases with each iteration
  5. Each node in the BMU's neighborhood has its weights adjusted to become more like the BMU. Nodes closest to the BMU are altered more than the nodes furthest away in the neighborhood
  6. Repeat from step 2 for enough iterations for convergence

# Self-Organizing Map (SOM)

- SOM: Learning
  2. Choose a random vector from training data and present it to the SOM
  3. Every node is examined to find the **Best Machine Unit (BMU)**

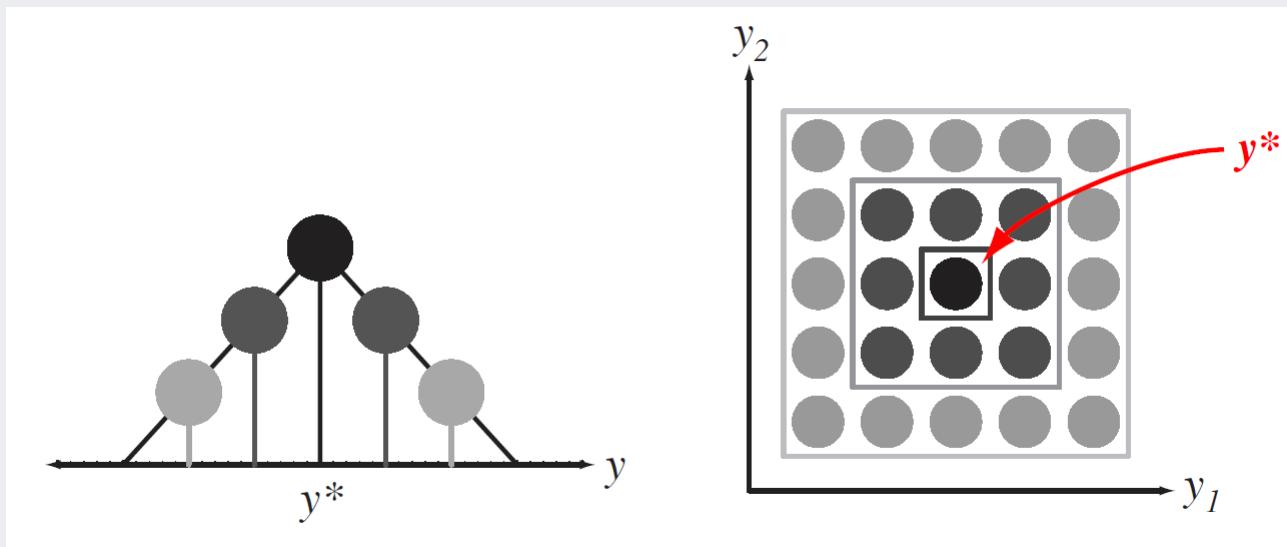

## A Text Example:

Self-organizing maps (SOMs) are a **data** visualization **technique** invented by Professor Teuvo Kohonen which reduce the dimensions of **data** through the use of **self-organizing** neural networks. The problem that data visualization attempts to solve is that humans simply cannot visualize high dimensional **data** as is so **technique** are created to help us understand this high dimensional **data**.

# Self-Organizing Map (SOM)

- SOM: Learning
4. The radius of the neighborhood around the BMU is calculated, the size of the neighborhood decreases with each iteration

# Self-Organizing Map (SOM)

- SOM: Learning
5. Each node in the BMU's neighborhood has its weights adjusted to become more like the BMU. Nodes closest to the BMU are altered more than the nodes furthest away in the neighborhood

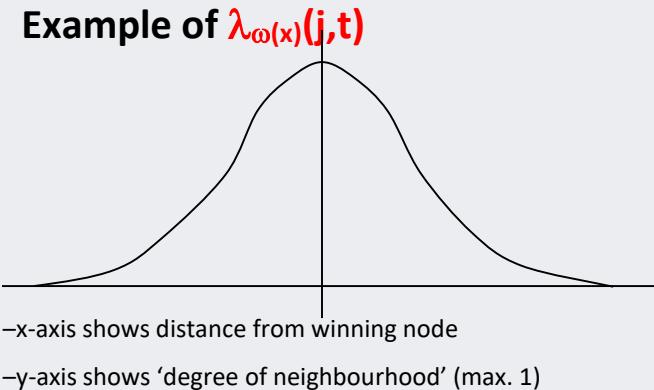

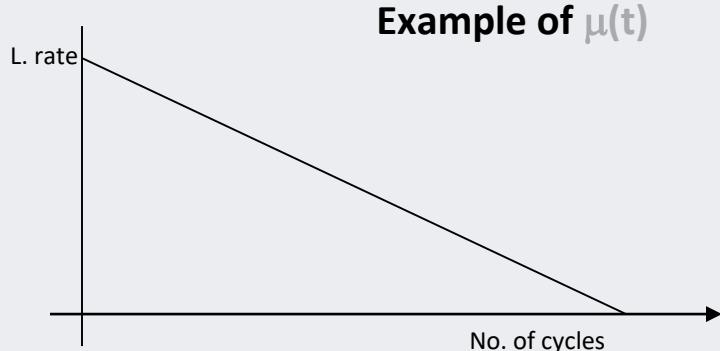

<SOM Weight Update Equation>

$$w_j(t+1) = w_j(t) + \mu(t) \lambda_{\omega(x)}(j,t) [x - w_j(t)]$$

“The weights of every node are updated at each cycle by adding

Current learning rate  $\times$  Degree of neighbourhood with respect to winner  $\times$  Difference between current weights and input vector

to the current weights”

# Self-Organizing Map (SOM)

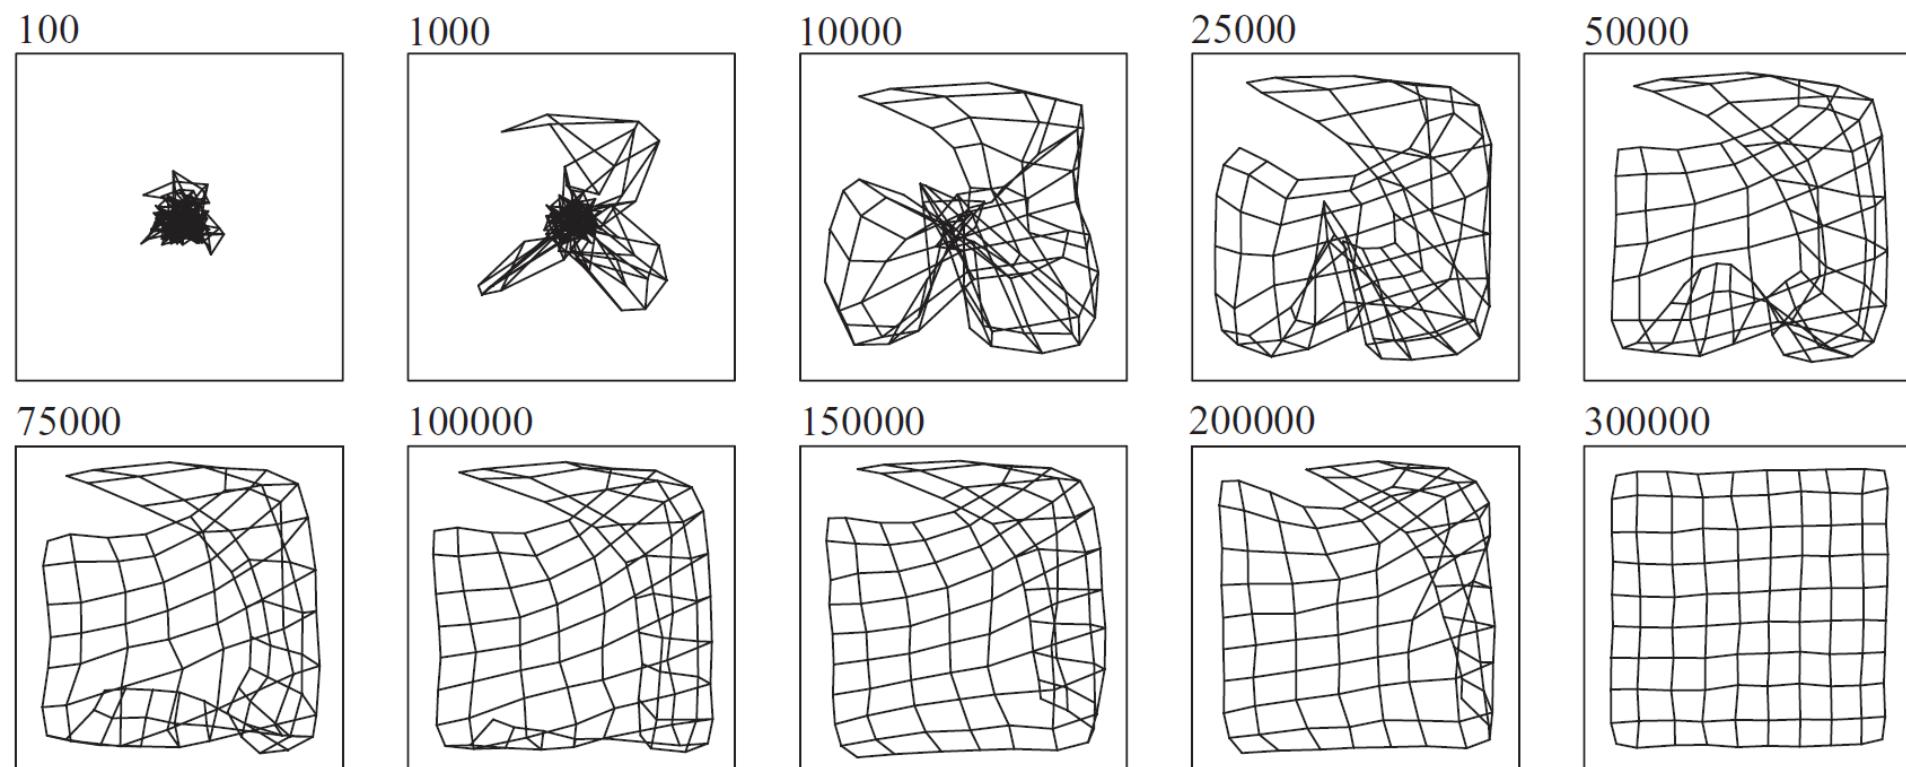

## Components of Self-Organization

1. Initialization
2. Competition
3. Cooperation
4. Adaptation

# Self-Organizing Map (SOM)

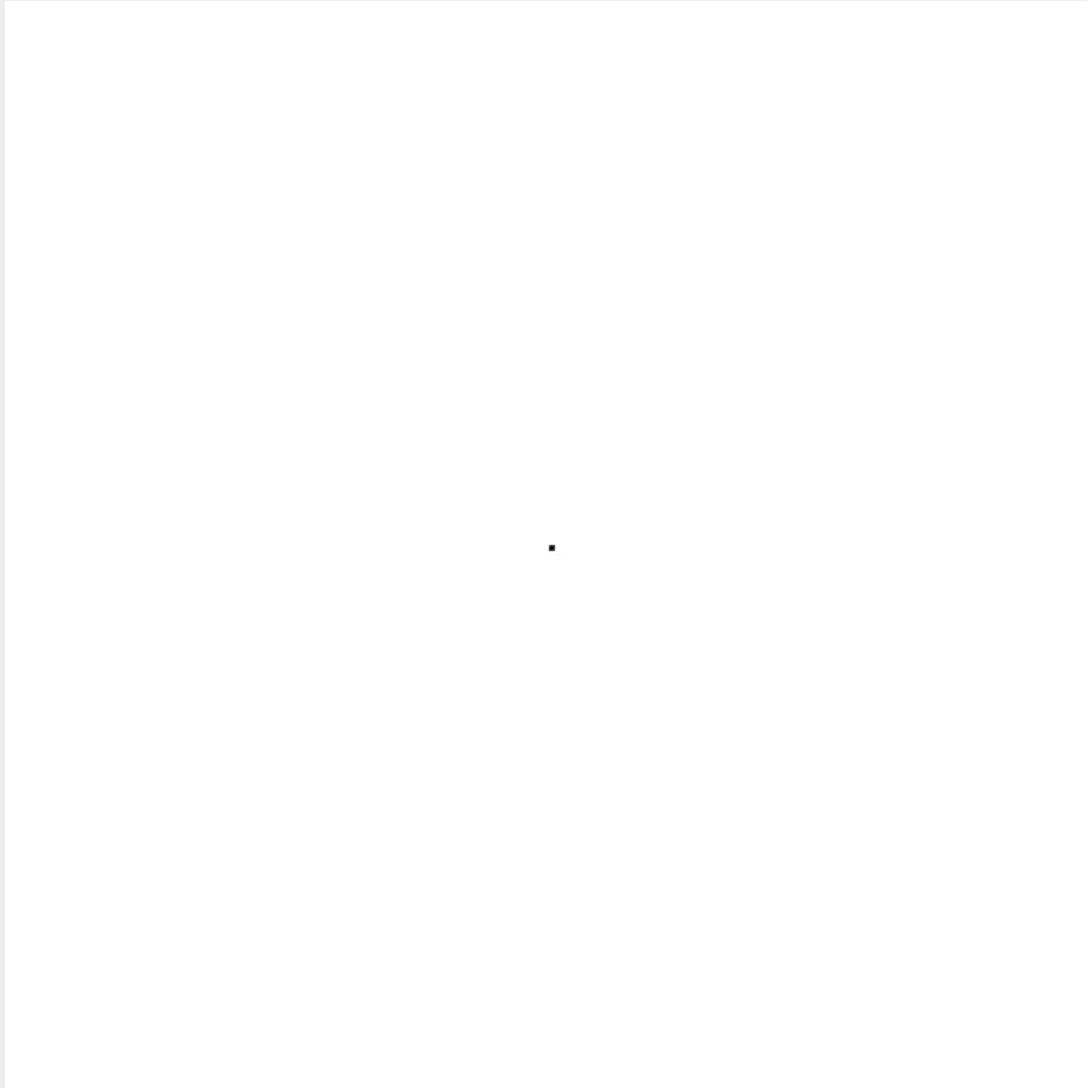

- SOM: Mapping through iterations

✓ Happily converges to...

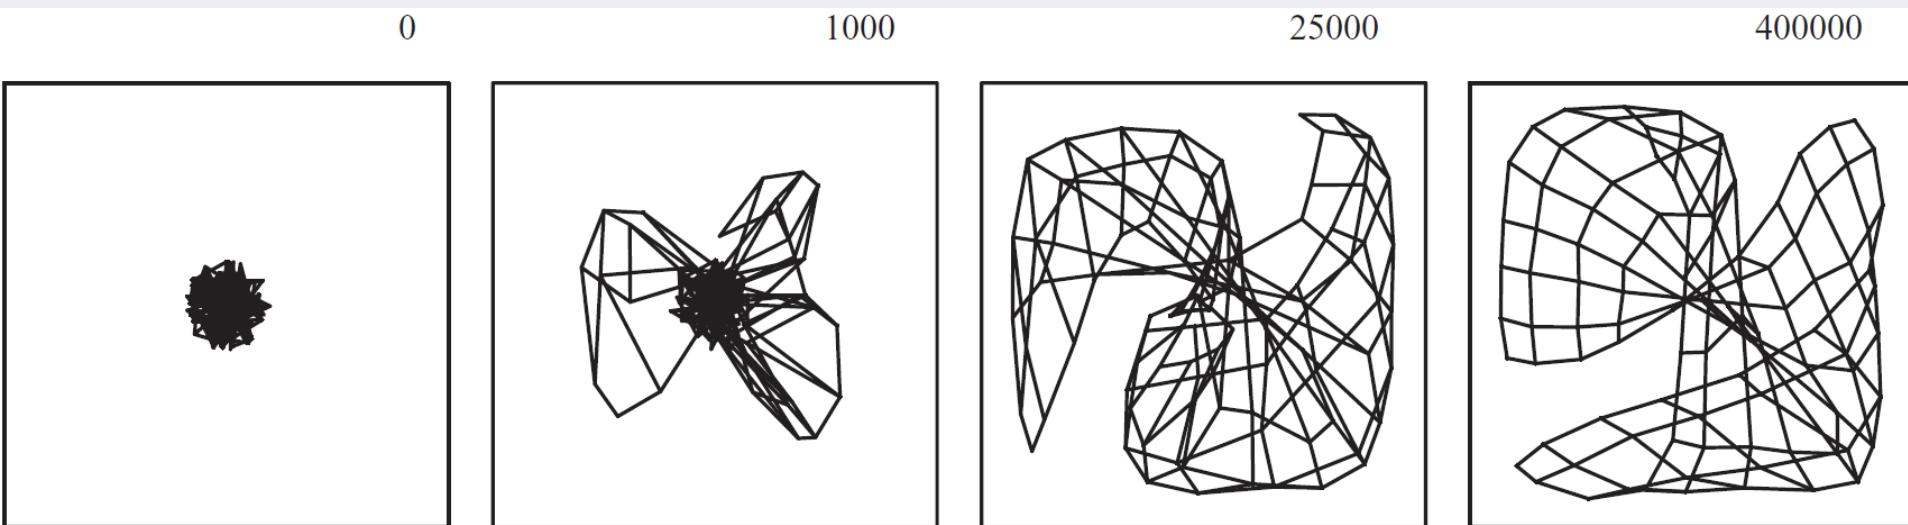

# Self-Organizing Map (SOM)

- Training SOM: Example

# Self-Organizing Map (SOM)

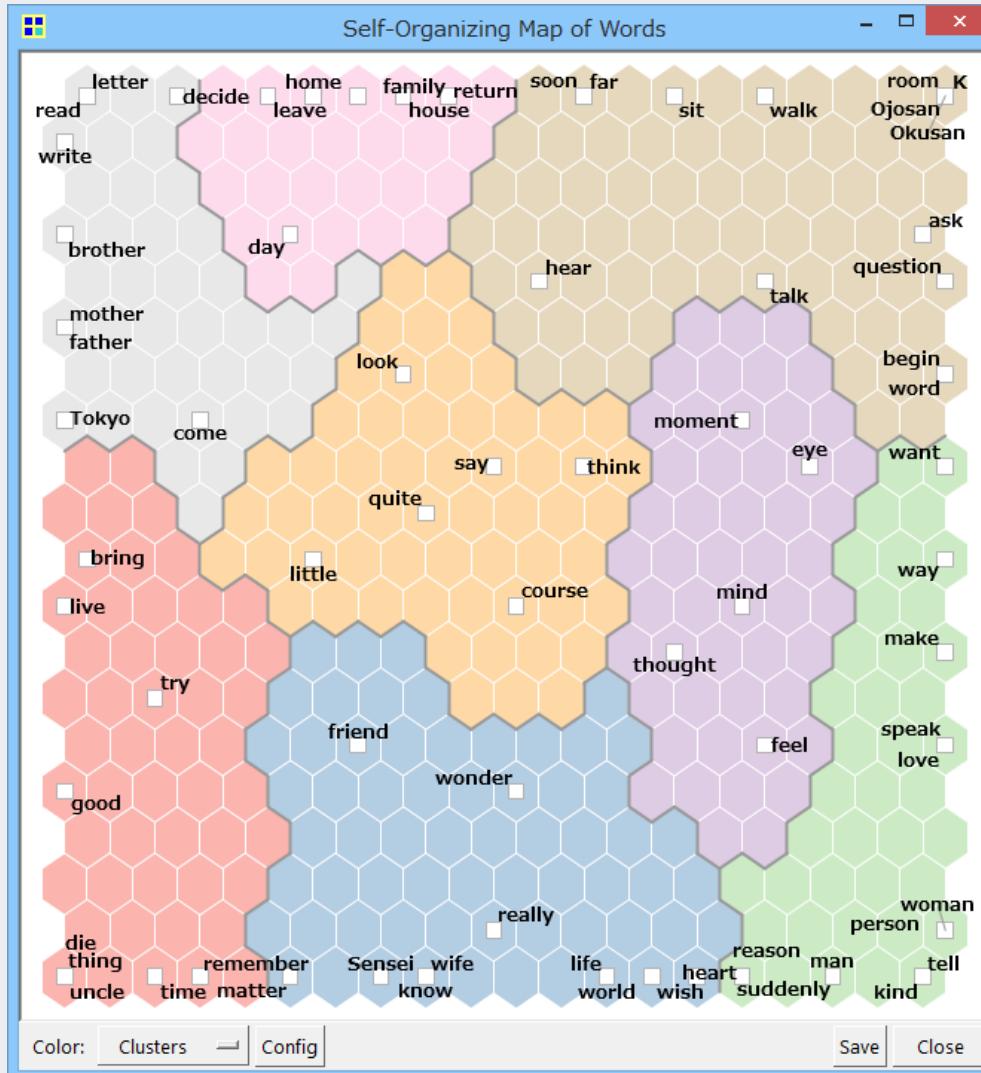

- SOM: Mapping through iterations
  - ✓ Unfortunately it happens sometimes...

✓ Initial weights should be regenerated!

# Case Studies

- Self-organizing map of words

ANY  
questions?

# Appendix A: Similarity/Distance Metrics for Binary Data
